We briefly report our calculation of the 2-loop coefficient of the coupling constant renormalization function $Z_g$ in lattice perturbation theory. The quantity under study is defined through $g_0 = Z_g g$, where $g_0$ ($g$) is the bare (renormalized) coupling constant. The 2-loop expression for $Z_g$ can be directly related to the 3-loop bare $\beta$-function $\beta_L(g_0)$.

Our calculation is performed using overlap fermions and Wilson gluons, and the background field technique has been chosen for convenience. Our results depend explicitly on the number of fermion flavors ($N_f$) and colors ($N$). Since the dependence of $Z_g$ on the overlap parameter $\rho$ cannot be extracted analytically, we tabulate our results for different values of $\rho$ in the allowed range ($0 < \rho < 2$), focusing on values which are being used most frequently in simulations.

Plots of the 1- and 2-loop results for $Z_g$ versus $\rho$ exhibit a non-trivial dependence on the overlap parameter.

A longer write-up of this work may be found in Ref.[1]:

1. INTRODUCTION

In later years, use of non-ultralocal actions which preserve chiral symmetry on the lattice has become more viable. The two actions which are being used most frequently are overlap fermions based on the Wilson fermion action and domain-wall fermions. Overlap fermions are notoriously difficult to study, both numerically and analytically. Many recent promising results from simulations with overlap fermions have appeared; see, e.g., Refs. [3]-[7]. Regarding analytical computations, the only ones performed thus far have been either up to 1 loop, such as Refs. [8]-[11], or vacuum diagrams at higher loops [12, 13]. The present work is the first one involving non-vacuum diagrams beyond the 1-loop level.

We compute the 2-loop renormalization $Z_g$ of the bare lattice coupling constant $g_0$ in the presence of overlap fermions. We relate $g_0$ to the renormalized coupling constant $g_{\overline{\text{MS}}}$ as defined in the $\overline{\text{MS}}$ scheme at a scale $\bar{\mu}$; at large momenta, these quantities are related as follows

$$a_{\overline{\text{MS}}} (\bar{\mu}) = a_0 + d_1 (\bar{\mu} a) a_0^2 + d_2 (\bar{\mu} a) a_0^3 + \ldots,$$  \hspace{1cm} (1.1)

$$a_{\text{MS}} (\bar{\mu}) = a_0 + d_1 (\bar{\mu} a) a_0^2 + d_2 (\bar{\mu} a) a_0^3 + \ldots$$  \hspace{1cm} (2.1)

The coefficients $a_0, b_1$ are well-known universal constants (regularization independent); $b_i$ ($i \geq 2$) (regularization dependent) must be calculated perturbatively. $\beta_{L}(g_0)$ and $\beta(g_{\overline{\text{MS}}})$ can be related using the renormalization function $Z_g$, that is
Thus, the evaluation of
equation (2.4), allows us to extract the 3-loop coefficient $b_{l}$
and inserting it in Eq. (2.4), allows us to extract the 3-loop coefficient $b_{l}$
and Wilson gluons. For completeness, we also compute the coefficient $7+11, 8+18, 9+17$.

except

Solid lines represent fermions.

Computing $Z_{g}^{2}$ to 2 loops

$$Z_{g}^{2}(g_{0}, a\bar{\mu}) = 1 + g_{0}^{2}(2b_{0}\ln(a\bar{\mu}) + l_{0}) + g_{0}^{4}(2b_{1}\ln(a\bar{\mu}) + l_{1}) + O(g_{0}^{6})$$

and inserting it in Eq. (2.4), allows us to extract the 3-loop coefficient $b_{l}$. All quantities in Eq. (2.5),
except $l_{1}$ (for overlap fermions), are known. The expansion of Eq. (2.4) in powers of $g_{0}^{2}$ provides
the following relation for $b_{l}$

$$b_{l} = b_{2} - b_{1}l_{0} + b_{0}l_{1}$$

Thus, the evaluation of $b_{l}^{2}$ requires only a 2-loop lattice calculation, of the quantity $l_{1}$.

The most convenient and economical way to proceed with the calculation of $Z_{g}(g_{0}, a\bar{\mu})$ is to
use the background field technique, in which the following relation is valid

$$Z_{A}(g_{0}, a\bar{\mu})Z_{g}^{2}(g_{0}, a\bar{\mu}) = 1$$

where $Z_{A}$ is the renormalized function of the background field. In the lattice version of the background
field technique, the link variable takes the form

$$U_{\mu}(x) = e^{i\mu_{0}a_{\mu}(x)} \cdot e^{i\mu A_{\mu}(x)}$$

($Q_{\mu}$: quantum field, $A_{\mu}$: background field). In this framework, instead of calculating $Z_{g}$, it suffices
to compute $Z_{A}$. For the above calculation, we consider the background field 1PI 2-point function,
both in the continuum and on the lattice; for notation and details, the reader can refer to [14]. The
gauge parameter $\lambda$ must also be renormalized, in order to compare lattice and continuum results

$$\lambda = Z_{Q} \lambda_{0}, \quad Z_{Q} = 1 + g_{0}^{2}z_{Q}^{(1)} + ...$$

($Z_{Q}$: renormalization function of the quantum field). Finally, $Z_{g}^{2}$ takes the form

$$Z_{g}^{2} = \left[1 + g_{0}^{2}(v_{R}^{(1)} - v^{(1)}) + g_{0}^{4}(v_{R}^{(2)} - v^{(2)}) + \lambda_{0} g_{0}^{4}z_{Q}^{(1)} \frac{\partial v_{R}^{(1)}}{\partial \lambda} \right]_{\lambda = \lambda_{0}}$$

($\lambda_{0} = 1$: bare Feynman gauge). Here, the only unknown quantity is $v^{(2)}$, the 2-loop 1PI lattice
Green’s function of the background field; its gluonic contribution ($N_{f}=0$) is known. One can find
the expressions for the remaining, known quantities in Ref. [1].

The fermionic contributions are associated with the diagrams of Fig. 1 ($v^{(1)}$) and Fig. 2 ($v^{(2)}$). In the present work, $v^{(2)}$ is perturbatively calculated for the first time using overlap fermions
and Wilson gluons. For completeness, we also compute the coefficient $v^{(1)}$ and compare it with
previous results. For overlap fermions, the mass counterterm (the filled circle in Fig. 2) equals zero,
by virtue of the exact chiral symmetry of the overlap action; consequently, diagrams 19 and 20 both
vanish. Diagrams with infrared divergences become convergent only when grouped together (6+12,
7+11, 8+18, 9+17).

3. OVERLAP ACTION

In recent years, overlap fermions are being used ever more extensively in numerical simulations, both in the quenched approximation and beyond. This fact, along with the desirable properties of the overlap action, was our motivation to calculate the $\beta$-function with this type of fermions. The important advantage of the overlap action is that it preserves chiral symmetry while avoiding fermion doubling. It is also $\theta'(a)$ improved. The main drawback of this action is that it is necessarily non-ultralocal; as a consequence, both numerical simulations and perturbative calculations are extremely difficult and demanding (in terms of human, as well as computer time).

The lattice overlap action is given by

$$S_{\text{overlap}} = a^8 \sum_{n,m} \Psi(n) D_N(n,m) \Psi(m)$$

where $D_N(n,m)$ is the overlap-Dirac operator

$$D_N(n,m) = \rho \left[ \frac{\delta_{n,m}}{a^4} - \left( X - \frac{1}{\sqrt{X'}} \right)_{nm} \right], \quad X = \frac{1}{a^4} (D_W - \rho)$$

and $D_W$ is the Wilson-Dirac operator. The overlap parameter $\rho$ is restricted by the condition $0 < \rho < 2$ to guarantee the correct pole structure of $D_N$. The coupling constant is included in the link variables, present in the definition of $X$, and one must take the perturbative expansion of $X$ in powers of $g_0$. This expansion in momentum space takes the form

$$X(p', p) = \chi_0(p)(2\pi)^4 \delta(p' - p) + X_1(p', p) + X_2(p', p) + X_3(p', p) + X_4(p', p) + O(g_0^5)$$

where $\chi_0$ is the inverse fermion propagator and $X_i$ are the vertices of the Wilson fermion action ($p$ ($p'$): fermion (antifermion) momentum). Inside of $X_i$'s there appear background and/or quantum gluon fields; their expressions are given in Ref. [1]. Upon substituting the expression for $X_i$'s in the overlap vertices, the latter become extremely lengthy and complicated. For instance, the vertex with $\text{Q-Q-A-A-} \Psi \Psi$ consists of 724,120 terms.

The perturbative expansion of $D_N$ leads to the propagator of zero mass fermions and to gluon-fermion-antifermion vertices (with up to 4 gluons for the needs of this calculation). After laborious analytical manipulations, the overlap-Dirac operator is expanded into terms with up to 4 gluons as
\[ D_N(k_1, k_2) = D_0(k_1) (2\pi)^4 \delta^4(k_1 - k_2) + \sum(k_1, k_2) \]  

(3.4)

\[ D_0(k_1) \] is the inverse propagator and \( \sum(k_1, k_2) \) leads to the vertices with up to 4 gluons. Due to the large size of \( \sum(k_1, k_2) \), its explicit form is given in Ref. [1].

4. RESULTS

For the algebra involving lattice quantities, we make use of our symbolic manipulation package in Mathematica, with the inclusion of the additional overlap vertices. The first step to evaluate the diagrams is the contraction among vertices; There follow simplifications of the color dependence, Dirac matrices and tensor structures. We use symmetries of the theory, or any other additional symmetry that may appear in particular diagrams, to keep the size of the expression down to a minimum. The external momentum \( p \) appears in arguments of trigonometric functions and the extraction of \( p \) dependence is divided into two parts: first we isolate terms that give single and double logarithms (a few thousand terms, expressible in terms of known, tabulated integrals) and then for the convergent terms we employ naive Taylor expansion with respect to \( p \) up to \( \mathcal{O}(p^2) \). The coefficients of terms proportional to \( p^2 \) must be numerically integrated over internal momenta. The integration is performed by optimized Fortran programs which are generated by our Mathematica ‘integrator’ routine. Each integral is evaluated for several lattices with varying lattice size and for different values of the overlap parameter \( \rho \). Finally, we extrapolate the results to infinite size lattices; this procedure introduces an inherent systematic error, which we can estimate quite accurately. Infrared divergent diagrams must be summed up before performing the extrapolation.

We denote the contribution of the \( i \)-th 1-loop Feynman diagram to \( \nu^{(1)}(p) \) as \( \nu_i^{(1)}(p) \); similarly, contributions of 2-loop diagrams to \( \nu^{(2)}(p) \) are indicated by \( \nu_i^{(2)}(p) \)

\[
\bar{a} p^2 \nu_i^{(1)}(p) = N_f \left[ k_i^{(0)} + a_1^2 p^2 k_i^{(1)} + a_2^2 p^2 k_i^{(2)} \right] + \mathcal{O}(a p^3) \\
\bar{a} p^2 \nu_i^{(2)}(p) = N_f \left[ c_i^{(0)} + a_1^2 p^2 c_i^{(1)} + a_2^2 p^2 c_i^{(2)} + a_3^2 p^2 c_i^{(3)} + a_4^2 p^2 c_i^{(4)} \right] + \mathcal{O}(a p^3)
\]

(4.1)

(4.2)

where \( \rho^2 = 4\sum \sin^2(p \mu/2) \). The index \( i \) runs over diagrams, and the coefficients \( k_i^{(j)}, c_i^{(j)} \) depend on the overlap parameter \( \rho \). Moreover, \( c_i^{(j)} = [c_i^{(j-1)} + N c_i^{(j+1)}] / N \). These coefficients must satisfy conditions coming from comparison with continuum results and usage of Ward Identities; we have checked that these conditions are verified by our results.

\[ \sum_i k_i^{(0)} = 0, \quad \sum_i k_i^{(1)} = 0, \quad \sum_i k_i^{(2)} = \frac{2}{3}, \quad \sum_i c_i^{(2)} = \frac{1}{16\pi^2}(3N - 1) \] 

(4.3)

\[ \sum_i c_i^{(4)} = 0, \quad c_{15}^{(3)} = \frac{1}{3N}, \quad c_{16}^{(3)} = \frac{4}{3N}, \quad c_{17}^{(3)} = \frac{-5}{3N}, \quad c_{18}^{(3)} = \frac{N^2 - 1}{3N} \] 

(4.4)

In Table I we tabulate the total 1- and 2-loop coefficients \( k_i^{(1)} \equiv \sum_i k_i^{(1)}, c_i^{(1, -1)} \equiv \sum_i c_i^{(1, -1)}, c_i^{(1, 1)} \equiv \sum_i c_i^{(1, 1)} \) for several values of the overlap parameter \( 0 < \rho < 2 \), after extrapolating to \( L \to \infty \). The results for \( k_i^{(1)} \) are in good agreement with corresponding results of Ref. [8]. In the Table and all Figures, the errors accompanying our results are entirely due to this extrapolation. In certain
cases with large systematic errors we extended the integration up to $L = 46$. In general, the overlap action leads to coefficients which are very small for most values of $r$. As a consequence, systematic errors, which are by and large rather small, tend to be significant fractions of the result for $r > 1.4$.
