We consider non-vanishing boundary conditions (NVBC) for the NLS model in the context of the hybrid dressing transformation and $\tau$-function approach. In order to write the NLS model in a suitable form to deal with non-vanishing boundary conditions it is introduced a new spectral parameter in such a way that the usual NLS parameter will depend on the affine parameter through the so-called Zukowsky function. In the context of the dressing transformation the introduction of the affine parameter avoids the construction of certain Riemann sheets for the usual NLS spectral parameter. In this way one introduces a Lax pair defined for the new spectral parameter and the relevant NVBC NLS $\tau$ functions are obtained by the dressing transformation method. We construct the one and two dark-soliton solutions explicitly.

The nonlinear Schrödinger model (NLS) with vanishing or non-vanishing boundary conditions is physically significant since it appears in many applications ranging from condensed matter to string theory (see e.g. [3]). The NLS model and its multifield extensions is an integrable system (see e.g. [5] and references therein). Here we provide the affine Kac-Moody algebraic formulation of the NLS model suitably written for non-vanishing boundary conditions and the hybrid of the dressing and Hirota methods is used to obtain dark soliton solutions of the model.

The convenient form of the NLS for dealing with non-vanishing boundary conditions, which support dark-soliton like solutions [6], can be written as

$$\partial_t \psi + \partial_{xx} \psi - 2(|\psi|^2 - \rho^2)\psi = 0. \tag{1}$$

This form of NLS model is supplied with the non-vanishing boundary conditions given by [1, 2, 3]

$$\psi = \begin{cases} \rho, & x \to -\infty, \\ \rho e^{i\varepsilon x}, & x \to +\infty \end{cases} \quad \rho = \text{real const., } \varepsilon = e^{i\theta}. \tag{2}$$

In order to give a group theoretical construction of the system above, let us consider the Lax pair $A$ and $B$

$$A = H^1 + \Psi^+ E^0_+ + \Psi^- E^0_+ + \Phi_1 C, \tag{3}$$
$$B = H^2 + \Psi^+ E^1_+ + \Psi^- E^1_+ + \partial \psi^+ E^0_+ - \partial \psi^- E^0_+ - 2(\psi^+ \psi^- - \rho^2)H^0 + \Phi_2 C, \tag{4}$$

where $\Psi^\pm$, $\Phi_1$ and $\Phi_2$ are the fields of the $\hat{s}(2)$ NLS model and the potential $A$ and $B$ lie in the $\hat{s}(2)$ affine Kac-Moody Lie algebra. The Lax pair in (3)-(5) provided with the zero-curvature condition

$$\partial_x B - \partial_y A - [A, B] = 0, \tag{5}$$

furnishes the model [1] provided that the following transformation $t \to \imag t, x \to \imag x, \psi^\pm \to \Psi^\pm e^{\imag \frac{x}{2}}$, and the identification $\psi \equiv \psi^+ = (\psi^-)^*$, are made. The factor $e^{\imag \frac{x}{2}}$ is introduced for later convenience and $*$ means complex conjugation. It was considered $\Psi^+_0 \Psi^-_0 = -\rho^2$.

The vacuum solutions to be considered are the ones of constant configuration, $\Psi^\pm_0 = \rho e^{\imag \frac{x}{2}}$, $\Phi_1 = \Phi_2 = 0$; so, the vacuum fields $A_V$ and $B_V$ from (3)-(8) are

$$A_V = H^1 + \rho e^{-\imag \frac{x}{2}} E^0_+ + \rho e^{\imag \frac{x}{2}} E^0_-, \quad B_V = H^2 + e^{-\imag \frac{x}{2}} \rho E^1_+ + e^{\imag \frac{x}{2}} \rho E^1_. \tag{6}$$

The vacuum connections can be written in the form

$$\hat{A}_V = \partial_x \Psi \Psi^{-1}, \quad \hat{B}_V = \partial_y \Psi \Psi^{-1}, \tag{7}$$

where $\Psi$ is the group element

$$\Psi = (\mathbb{I} + k^+ E_+ - k^- E_-)e^{\imag \zeta \sigma_3} e^{\imag \kappa \sigma_1}, \tag{8}$$

with $k^\pm$ being constants, $\mathbb{I}$ the identity matrix and $E_{\pm}$, $\sigma_3$ Pauli matrices. The connections in (7) are called pure gauge solutions and are solutions of the zero-curvature condition (6).

Considering a $2 \times 2$ matrix representation for (8) in $\hat{s}(2)$ algebra, it is possible to write certain relationships between the parameters $k^+, k^-, \zeta, \kappa$ and $\lambda$

$$\kappa = \lambda \zeta, \quad k^\pm = -2\rho e^{\imag \frac{x}{2}} \frac{1}{\lambda + 2\zeta}, \quad 4\zeta^2 = 4\rho^2 + \lambda^2. \tag{9}$$
The relationships in (10) show that \( \zeta \) and \( \kappa \) assume two possible values in terms of \( \lambda \), this requires the construction of Riemann sheets. Here it is introduced an affine parameter \( \xi \) such that the functions
\[
\zeta = \frac{1}{2} \left( \xi + \frac{\rho^2}{\xi} \right), \quad \lambda = \xi \frac{\rho^2}{\xi}, \quad \kappa = \frac{1}{2} \left( \xi^2 - \frac{\rho^4}{\xi^2} \right), \quad k^\pm = -\xi^\pm 2.
\]
become single valued in terms of \( \xi \). The function \( \zeta(\xi) \) above is known as the Zukowsky function.

The appearance of an affine parameter motivates us to introduce a new spectral parameter associated with the potentials \( \hat{A} \) and \( \hat{B} \)
\[
\hat{A} = H^1 - \rho^2 H^{-1} + \Psi^+ E_+^0 + \Psi^- E_-^0 + \phi_1 C, \tag{11}
\]
\[
\hat{B} = H^2 + \rho^4 H^{-2} + \Psi^+ (E_+^1 - \rho^2 E_+^{-1}) + \Psi^- (E_-^1 - \rho^2 E_-^{-1})
+ \partial_1 \Psi^+ E_+^0 - \partial_1 \Psi^+ E_+^0 - 2 \Psi^+ \Psi^- H^0 + \phi_2 C. \tag{12}
\]
The potentials (11) and (12) written in terms of the new spectral parameter \( \xi \) describe the NLS model (1) when the zero-curvature condition (5) is used. So, the vacuum connections corresponding to (11) and (12) are given by
\[
\hat{A}_V = H^1 - \rho^2 H^{-1} + \rho \epsilon^2 E_+^0 + \rho \epsilon^2 E_-^0, \tag{13}
\]
\[
\hat{B}_V = H^2 + \rho^4 H^{-2} + \rho \epsilon^2 (E_+^1 - \rho^2 E_+^{-1}) + \rho \epsilon^2 (E_-^1 - \rho^2 E_-^{-1}) - 2 \rho^2 H^0. \tag{14}
\]
Notice that these potentials are deformations of the ones in (8).

In terms of the new spectral parameter \( \xi \), (8) takes the form
\[
\Psi = P e^{\lambda (H^1 + \rho^2 H^{-1})} e^{\xi (H^2 - \rho^4 H^{-2})}, \tag{15}
\]
where
\[
P = 1 - \rho \epsilon^2 E_+^{-1} + \rho \epsilon^2 E_-^{-1}, \quad P^{-1} = \frac{1}{1 + \frac{\epsilon^2}{\xi^2}} (1 + \epsilon^2 \rho E_+^{-1} - \epsilon^2 \rho E_-^{-1}). \tag{16}
\]
When \( \rho \to 0 \) one has \( \xi \to \lambda \), which implies that \( P \to 1 \).

1. The dressing transformation

The dressing transformations are non-local gauge transformations that act on the fields of the model preserving their gradation structure; they are made with the aid of two group elements \( \Theta_+ \) and \( \Theta_- \), such that
\[
\hat{A} \to \hat{A}^h = \Theta_+ \hat{A} \Theta_+^{-1} + \partial_1 \Theta_+ \Theta_-^{-1},
\]
\[
\hat{B} \to \hat{B}^h = \Theta_+ \hat{B} \Theta_+^{-1} + \partial_1 \Theta_+ \Theta_-^{-1}. \tag{1.1}
\]
It is assumed the generalized Gauss decomposition
\[
\Psi h \Psi^{-1} = (\Psi h \Psi^{-1})_- (\Psi h \Psi^{-1})_0 (\Psi h \Psi^{-1})_+ \equiv \Theta^- \hat{M} \hat{N}. \tag{1.2}
\]
The vector tau function $\vec{\tau}(x,t)$ is defined by [1]

$$\vec{\tau}(x,t) = (\Psi h \Psi^{-1})_0 |\hat{\lambda}_0\rangle = \Theta^{-1} \hat{M}^{-1} |\hat{\lambda}_0\rangle.$$  \hfill (1.3)

Once the highest weight state $|\hat{\lambda}_0\rangle$ is an eigenstate of $\hat{g}_0$ subalgebra, it is possible to define

$$\vec{\tau}_0(x,t) = \hat{M}^{-1} |\hat{\lambda}_0\rangle = |\hat{\lambda}_0\rangle \vec{\tau}_0(x,t),$$  \hfill (1.4)

where $\vec{\tau}_0(x,t)$ is a function described by

$$\vec{\tau}_0(x,t) = (\hat{\lambda}_0 |(\Psi h \Psi^{-1})_0 |\hat{\lambda}_0\rangle.$$  \hfill (1.5)

Using (1.3) and (1.5) one finds

$$\Theta^{-1} |\hat{\lambda}_0\rangle = \frac{\vec{\tau}(x,t)}{\vec{\tau}_0(x,t)}. \hfill (1.6)$$

Replacing the fields $A_V$ and $B_V$, in the form given in [3], into the dressing transformation (1.1), one gets

$$\hat{\lambda}^h = \Theta_-(H^1 - \rho^2 H^{-1} + \rho \epsilon^{-2} E_0^1 + \rho \epsilon^2 E_0^-) \Theta^{-1} + \partial_\lambda \Theta \Theta^{-1} \hfill (1.7)$$
$$\hat{B}^h = \Theta_-(H^2 + \rho^4 H^{-2} + \rho \epsilon^{-2} (E_1^1 - \rho^2 E_1^-)
\quad + \rho \epsilon^2 (E_1^- - \rho^2 E_1^1) - 2 \rho^2 \hat{H}^0) \Theta_- + \partial_\lambda \Theta \Theta^{-1} \hfill (1.8)$$

where $\Theta_+ = \exp \left(\sum_{n>0} \sigma_- n\right), \hat{M} = \exp(\hat{\sigma}_0)$ and $\hat{N} = \exp(\sum_{n<0} \sigma_n)$. It is possible to find some of the components, say $\hat{\sigma}_{-1}, \hat{\sigma}_{-2}$, in terms of the fields $\Psi^\pm, \phi_1$ and $\phi_2$

$$\hat{\sigma}_{-1} = -\left(\Psi^+ - \rho \epsilon^{-2}\right) E_1^- + \left(\Psi^- - \rho \epsilon^2\right) E_1^+ + \sigma_1 H^{-1}, \hfill (1.9)$$
$$\hat{\sigma}_{-2} = -\sigma_2 E_2^- + \left(\Psi^- - \rho \epsilon^2\right) E_1^- + \sigma_1 H^{-1}, \hfill (1.10)$$

one finds $\partial_\lambda \sigma_1^0 = 2(\Psi^+ \Psi^- - \rho^2), \sigma_2^0 = -\partial_\lambda \Psi^\pm + \frac{1}{2} \sigma_0^0 \Psi^\pm, \phi_1 = -\frac{1}{2} \sigma_0^1$ and $\phi_2 = -\sigma_0^2$. So, with the aid of [17], the solutions in the orbit of the vacuum are given by

$$\Psi^+ = \rho \epsilon^{-2} + \frac{\hat{\tau}^+}{\hat{\tau}_0}, \quad \Psi^- = \rho \epsilon^2 - \frac{\hat{\tau}^-}{\hat{\tau}_0}, \hfill (1.11)$$

where the $\tau^\pm$ functions are defined by

$$\hat{\tau}^+ = \langle \hat{\lambda}_0 | E_1^+ (\Psi h \Psi^-)^{-1} | \hat{\lambda}_0 \rangle, \hfill (1.12)$$
$$\hat{\tau}^- = \langle \hat{\lambda}_0 | E_1^- (\Psi h \Psi^-)^{-1} | \hat{\lambda}_0 \rangle. \hfill (1.13)$$

According to the dressing method, the soliton solutions are determined by choosing convenient constant group elements $h$. 

Nonvanishing boundary conditions and dark solitons in the NLS model

PoS(ISFTG)043

4
In order to get insight into the ‘dark’-soliton evolution let us plot the function successive times. The figure 1 is plotted for $\tau = \tau + 1$. The 1-dark soliton solution

Nonvanishing boundary conditions and dark solitons in the NLS model

or the integrable highest weight representations of the Kac-Moody algebra. Similarly, one can set $h = e^G$, where $G = \sum_{n=-\infty}^{\infty} \rho_n^2 E_n^-$. In this way one can get another one dark-soliton solution. In order to get insight into the ‘dark’-soliton evolution let us plot the function $(\Psi^+\Psi^-)$ for two successive times. The figure 1 is plotted for $a_1 = -2; \nu_1 = 1.9, \epsilon = 1, \rho = 2, \eta_1 = -1.8, and c_1 = 0.5$. Notice the nonvanishing boundary condition for the fields at $x \rightarrow \pm \infty$ in the figure above.

1.2 The 2-dark soliton solution

In order to obtain 2-soliton solution it is chosen $h = e^F e^G$. The relevant $\tau$ functions become

$$
\tau^0 = 1 + a_1 e^{-\varphi} \langle \hat{\lambda}_0 | PFP^{-1} | \hat{\lambda}_0 \rangle + a_2 e^{\eta} | \hat{\lambda}_0 | PGP^{-1} | \hat{\lambda}_0 \rangle + a_3 e^{\eta_1 - \varphi} \langle \hat{\lambda}_0 | PFP^{-1} | \hat{\lambda}_0 \rangle, \quad (1.19)
$$

$$
\tau^+ = b_1 e^{-\varphi} \langle \hat{\lambda}_0 | E^1_+ (PFP^{-1}) | \hat{\lambda}_0 \rangle + b_2 e^{\eta_1} \langle \hat{\lambda}_0 | E^1_+ (PGP^{-1}) | \hat{\lambda}_0 \rangle + b_3 e^{\eta_1 - \varphi} \langle \hat{\lambda}_0 | E^1_+ (PFP^{-1}) | \hat{\lambda}_0 \rangle, \quad (1.20)
$$

$$
\tau^- = c_1 e^{-\varphi} \langle \hat{\lambda}_0 | E^1_+ (PFP^{-1}) | \hat{\lambda}_0 \rangle + c_2 e^{\eta_1} \langle \hat{\lambda}_0 | E^1_+ (PGP^{-1}) | \hat{\lambda}_0 \rangle + c_3 e^{\eta_1 - \varphi} \langle \hat{\lambda}_0 | E^1_+ (PFP^{-1}) | \hat{\lambda}_0 \rangle. \quad (1.21)
$$

Figure 1: 1-dark soliton evolution for two successive times showing the NVBCs.
As usual the matrix elements above can be computed through the relevant highest weight representation of the affine Lie algebra, however one can avoid those calculations by writing these matrix elements as certain constant parameters which must be determined by direct replacement of the solutions into the relevant equations of motion. These cumbersome computations can be made with the aid of a program such as MAPLE. So, one gets the solutions $\psi^+$ and $\psi^-$ given by

$$\psi^+ = \rho \varepsilon^{-2} + \frac{a_1 \varepsilon^{-\phi_1} + a_2 \varepsilon^{\eta_1} + a_2 d_1 \varepsilon^{(m_1+\nu_1)(\rho^2+m_1\nu_1)} e^{-\phi_1 \varepsilon^{\eta_1}}}{1 - \frac{\varepsilon^{-\phi_1}}{\varepsilon^{\phi_1}}} \varepsilon^{\eta_1} \quad \frac{(m_1+\nu_1)(\rho^2+m_1\nu_1)}{\rho^2+m_1\nu_1} \varepsilon^{\eta_1}$$

and

$$\psi^- = \rho \varepsilon^2 + \frac{a_1 \varepsilon^{\phi_1} + a_2 \varepsilon^{\eta_1} + a_1 d_2 \varepsilon^{(m_1-\nu_1)(\rho^2+m_1\nu_1)} e^{-\phi_1 \varepsilon^{\eta_1}}}{1 - \frac{\varepsilon^{\phi_1}}{\varepsilon^{-\phi_1}}} \varepsilon^{\eta_1} \quad \frac{(m_1-\nu_1)(\rho^2+m_1\nu_1)}{\rho^2+m_1\nu_1} \varepsilon^{\eta_1}$$

where $\phi_1 = x(\nu_1 + \frac{\rho^2}{\nu_1}) + (\frac{\rho^2}{\nu_1})$, $\eta_1 = x(m_1 + \frac{\rho^2}{m_1}) + (m_1 - \rho^4/m_1)$, and $r_2 = \rho \varepsilon^2$. The corresponding 2-dark soliton evolution can be visualized by plotting the function $(\psi^+ \psi^-)$ for certain parameter values (see Fig. 2).
