We study the effect of a potential fourth fermion generation on the upper and lower Higgs boson mass bounds. This investigation is based on the numerical evaluation of a chirally invariant lattice Higgs-Yukawa model emulating the same Higgs-fermion coupling structure as in the Higgs sector of the electroweak Standard Model. In particular, the considered model obeys a Ginsparg-Wilson version of the underlying $SU(2)_L \times U(1)_Y$ symmetry, being a global symmetry here due to the neglect of gauge fields in this model. We present our results on the modification of the upper and lower Higgs boson mass bounds induced by the presence of a hypothetical very heavy fourth quark doublet. Finally, we compare these findings to the standard scenario of three fermion generations.

1. Introduction

The Sakharov explanation for the matter anti-matter asymmetry of the universe suffers from the CP-violating phase of the Standard Model (SM3) falling short by at least 10 orders of magnitude. In addition to this concern the Sakharov picture demands a first order electroweak phase transition, which is also objected in the framework of the SM3. However, both of the above caveats might be addressable [1, 2] by the inclusion of a new fourth fermion generation into an extended version of the Standard Model (SM4). Despite the arguments against the existence of a fourth fermion generation such a scenario nevertheless remains attractive for two reasons. Firstly, there is a strong conceptual interest, since a new fermion generation would need to be very heavy, leading to rather large Yukawa coupling constants and thus to potentially strong interactions with the scalar sector of the theory. Secondly, it has been argued [1] (and the references therein) that the fourth fermion generation is actually *not* excluded by electroweak precision measurements, thus leaving the potential existence of a new fermion generation an open question.

In our contribution, however, we do not present any statement arguing in favour or disfavour of a new fermion generation. Here, we simply assume its existence and focus on the arising consequences on the Higgs boson mass spectrum. With the advent of the LHC this question will become of great phenomenological interest, since the Higgs boson mass bounds, in particular the lower bound, depend significantly on the heaviest fermion mass. Demonstrating this effect will be the main objective of the present work.

Due to the large Yukawa coupling constants of the fourth fermion generation a non-perturbative computation is highly desirable. For this purpose we employ a lattice approach to investigate the strong Higgs-fermion interaction. In fact, we follow here the same lattice strategy that has already been used in Ref. [3] for the non-perturbative determination of the upper and lower Higgs boson mass bounds in the SM3. This latter approach has the great advantage over the preceding lattice studies of Higgs-Yukawa models that it is the first being based on a consistent formulation of an exact lattice chiral symmetry [4], which allows to emulate the chiral character of the Higgs-fermion coupling structure of the Standard Model on the lattice in a conceptually fully controlled manner.

2. Numerical Results

In order to evaluate the Higgs boson mass bounds we have implemented a lattice model of the pure Higgs-fermion sector of the Standard Model. To be more precise, the Lagrangian of the targeted Euclidean continuum model we have in mind is given as

$$L_{HY} = \bar{t}' \not{\partial} t' + \bar{b}' \not{\partial} b' + \frac{1}{2} \partial_\mu \varphi^\dagger \partial_\mu \varphi + \frac{1}{2} m_0^2 \varphi^\dagger \varphi + \lambda (\varphi^\dagger \varphi)^2 + y_{b'} (\bar{t}', \bar{b}')_L \varphi b'_R + y_{t'} (\bar{t}', \bar{b}')_L \tilde{\varphi} t'_R + \text{c.c. of Yukawa interactions}, \quad (2.1)$$

where we have constrained ourselves to the consideration of the heaviest quark doublet, *i.e.* the fourth generation doublet, which is labeled here (t', b') . This restriction is reasonable, since the dynamics of the complex scalar doublet φ ($\tilde{\varphi} = i\tau_2 \varphi^*$, τ_i : Pauli-matrices) is dominated by the coupling to the heaviest fermions. For the same reason we also neglect any gauge fields in this approach. The quark fields nevertheless have a colour index which actually leads to $N_c = 3$ identical

copies of the fermion doublet appearing in the model. However, for a first exploratory study of the fermionic influence on the Higgs boson mass bounds we have set N_c to 1 for simplicity.

The actual lattice implementation of the continuum model in Eq. (2.1) has been discussed in detail in Ref. [3]. Since the Yukawa interaction has a chiral structure, it is important to establish chiral symmetry also in the lattice approach. This has been a long-standing obstacle, which was finally found to be circumventable by constructing the lattice equivalent of \not{D} as well as the left- and right-handed components of the quark fields $t'_{L,R}, b'_{L,R}$ on the basis of the Neuberger overlap operator [4, 5]. Following the proposition in Ref. [4] we have constructed a lattice Higgs-Yukawa model with a global $SU(2)_L \times U(1)_Y$ symmetry.

The fields considered in this model are the aforementioned doublet ϕ as well as N_c quark doublets represented by eight-component spinors $\bar{\psi}^{(i)} \equiv (\bar{t}'^{(i)}, \bar{b}'^{(i)})$, $i = 1, \dots, N_c$. With $\mathcal{D}^{(ov)}$ denoting the Neuberger overlap operator the fermionic action S_F can be written as

$$S_F = \sum_{i=1}^{N_c} \bar{\psi}^{(i)} \mathcal{M} \psi^{(i)}, \quad \mathcal{M} = \mathcal{D}^{(ov)} + P_+ \phi^\dagger \text{diag}(y_{t'}, y_{b'}) \hat{P}_+ + P_- \text{diag}(y_{t'}, y_{b'}) \phi \hat{P}_-, \quad (2.2)$$

where $y_{t'}, y_{b'}$ denote the Yukawa coupling constants and the scalar field ϕ_x has been rewritten here as a quaternionic, 2×2 matrix $\phi_x^\dagger = (\bar{\phi}_x, \phi_x)$, with x denoting the site index of the $L_s^3 \times L_t$ -lattice. The left- and right-handed projection operators P_\pm and the modified projectors \hat{P}_\pm are given as

$$P_\pm = \frac{1 \pm \gamma_5}{2}, \quad \hat{P}_\pm = \frac{1 \pm \hat{\gamma}_5}{2}, \quad \hat{\gamma}_5 = \gamma_5 \left(\mathbb{1} - \frac{1}{\rho} \mathcal{D}^{(ov)} \right), \quad (2.3)$$

with ρ being the radius of the circle of eigenvalues in the complex plane of the free Neuberger overlap operator [5].

This action now obeys an exact global $SU(2)_L \times U(1)_Y$ lattice chiral symmetry. For $\Omega_L \in SU(2)$ and $\varepsilon \in \mathbb{R}$ the action is invariant under the transformation

$$\psi \rightarrow U_Y \hat{P}_+ \psi + U_Y \Omega_L \hat{P}_- \psi, \quad \bar{\psi} \rightarrow \bar{\psi} P_+ \Omega_L^\dagger U_Y^\dagger + \bar{\psi} P_- U_Y^\dagger, \quad (2.4)$$

$$\phi \rightarrow U_Y \phi \Omega_L^\dagger, \quad \phi^\dagger \rightarrow \Omega_L \phi^\dagger U_Y^\dagger \quad (2.5)$$

with the compact notation $U_Y \equiv \exp(i\varepsilon Y)$ denoting the respective representations of the global hypercharge symmetry group $U(1)_Y$ for the respective field it is acting on. In the continuum limit Eq. (2.4-2.5) eventually recover the (here global) continuum $SU(2)_L \times U(1)_Y$ chiral symmetry.

Finally, the purely bosonic part S_ϕ of the total lattice action $S = S_F + S_\phi$ is given by the usual lattice ϕ^4 -action

$$S_\phi = \sum_x \frac{1}{2} \nabla_\mu^f \phi_x^\dagger \nabla_\mu^f \phi_x + \frac{1}{2} m_0^2 \phi_x^\dagger \phi_x + \lambda (\phi_x^\dagger \phi_x)^2, \quad (2.6)$$

with the bare mass m_0 , the forward difference operator ∇_μ^f in direction μ , and the bare quartic coupling constant λ . For the practical lattice implementation, however, a reformulation of Eq. (2.6) in terms of the hopping parameter κ and the lattice quartic coupling constant $\hat{\lambda}$ proves to be more convenient. It reads

$$S_\phi = -\kappa \sum_{x,\mu} \Phi_x^\dagger [\Phi_{x+\mu} + \Phi_{x-\mu}] + \sum_x \Phi_x^\dagger \Phi_x + \hat{\lambda} \sum_x (\Phi_x^\dagger \Phi_x - N_c)^2, \quad (2.7)$$

and is fully equivalent to Eq. (2.6). This alternative formulation opens the possibility of explicitly studying the limit $\lambda = \infty$ on the lattice. The aforementioned connection can be established through a rescaling of the scalar field $\Phi_x \in \mathbb{R}^4$ and the involved coupling constants according to

$$\varphi_x = \sqrt{2\kappa} \begin{pmatrix} \Phi_x^2 + i\Phi_x^1 \\ \Phi_x^0 - i\Phi_x^3 \end{pmatrix}, \quad \lambda = \frac{\hat{\lambda}}{4\kappa^2}, \quad m_0^2 = \frac{1 - 2N_c\hat{\lambda} - 8\kappa}{\kappa}. \quad (2.8)$$

Due to the triviality of the Higgs sector the targeted Higgs boson mass bounds actually depend on the non-removable, intrinsic cutoff parameter Λ of the considered Higgs-Yukawa theory, which can be defined as the inverse lattice spacing, *i.e.* $\Lambda = 1/a$. To determine these cutoff dependent bounds for a given phenomenological scenario, *i.e.* for given hypothetical masses of the fourth fermion generation, the strategy is to evaluate the maximal interval of Higgs boson masses attainable within the framework of the considered Higgs-Yukawa model being in consistency with this phenomenological setup. The free parameters of the model, being the bare scalar mass m_0 , the bare quartic coupling constant λ , and the Yukawa coupling constants $y_{t',b'}$ thus have to be tuned accordingly. The idea is to use the phenomenological knowledge of the renormalized vacuum expectation value $v_r/a = 246\text{GeV}$ of the scalar field φ as well as the hypothetical fourth generation quark masses $m_{t',b'}$ to fix the bare model parameters for a given cutoff Λ .

In lack of an additional matching condition a one-dimensional freedom is left open here, which can be parametrized in terms of the quartic coupling constant λ . This freedom finally leads to the emergence of upper and lower bounds on the Higgs boson mass. As expected from perturbation theory, one also finds numerically [3] that the lightest and heaviest Higgs boson masses are obtained at vanishing and infinite bare quartic coupling constant, respectively. The lower mass bound will therefore be obtained at $\lambda = 0$, while $\lambda = \infty$ will be adjusted to derive the upper bound.

Concerning the hypothetical masses of the fourth fermion generation quarks, we target here a mass degenerate scenario with $m_{t'}/a = m_{b'}/a = 700\text{GeV}$, which is somewhat above its tree-level unitarity upper bound [6]. However, we are currently also investigating a set of other mass settings to study in particular the quark mass dependence of the Higgs boson mass bounds.

Table 1: The model parameters underlying the lattice calculations performed in this study are presented. The setting $\lambda = 0$ ($\lambda = \infty$) is employed for deriving the lower (upper) Higgs boson mass bound. Depending on the lattice volume the available statistics ranges from $N_{Conf} = 1,000$ to $N_{Conf} = 20,000$.

For the eventual determination of the cutoff dependent Higgs boson mass bounds several series of Monte-Carlo calculations have been performed at different values of Λ and on different lattice volumes as summarized in Tab. 1. In order to tame finite volume effects as well as cutoff effects to an acceptable level, we have demanded as a minimal requirement that all particle masses $\hat{m} = m_H, m_{t'}, m_{b'}$ in lattice units fulfill $\hat{m} < 0.5$ and $\hat{m} \cdot L_{s,t} > 3.5$, at least on the largest investigated lattice volumes. Assuming the Higgs boson mass m_H to be around 500 – 750 GeV this allows to reach cutoff scales between 1500 GeV and 3500 GeV on a $24^3 \times 32$ -lattice. However, despite this setting strong finite volume effects are nevertheless expected induced by the massless Goldstone modes. It is known that these finite size effects are proportional to $1/L_s^2$ at leading order. An infinite volume extrapolation of the lattice data is therefore mandatory.

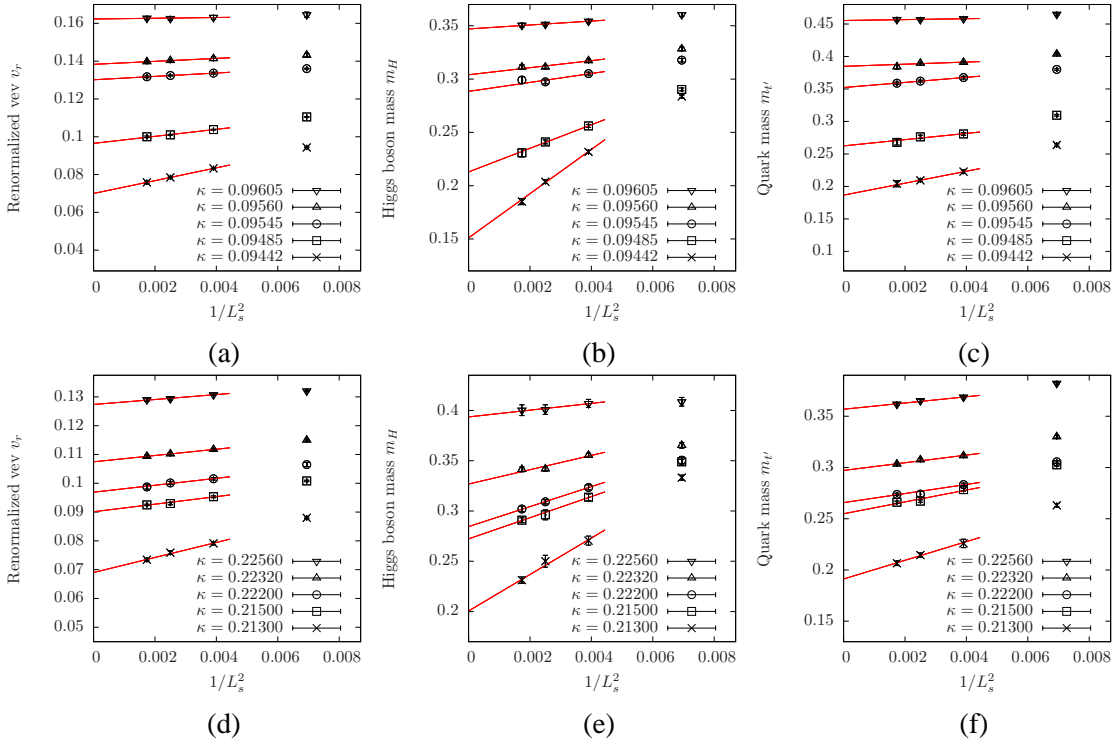

Figure 1: The finite volume data of the renormalized vacuum expectation value v_r (a,d), the Higgs boson mass m_H (b,e), and the degenerate quark mass $m_{t'} = m_{b'}$ (c,f), as obtained from the lattice calculations specified in Tab. 1, are plotted versus $1/L_s^2$. The upper (lower) row corresponds to the setting $\lambda = 0$ ($\lambda = \infty$). The infinite volume extrapolation is performed by fitting the data to a linear function. Due to the observed curvature arising from the non-leading finite volume corrections only those data with $L_s \geq 16$ have been respected by the linear fit procedures.

The finite volume data of the renormalized vacuum expectation value v_r , the Higgs boson mass m_H , and the degenerate quark mass $m_{t'} = m_{b'}$ resulting from the calculations specified in Tab. 1 are presented in Fig. 1. For the details about the determination of the latter observables the interested reader is referred to Ref. [3]. Here it is only stated that the renormalization constant Z_G entering the renormalization of the scalar field ϕ has been derived from the Goldstone propagator, the Higgs boson mass m_H has been taken from the Higgs propagator, and the quark masses have

been computed from the time correlation function of the respective fermionic fields. These lattice data are plotted versus $1/L_s^2$ and extrapolated to the infinite volume limit by means of a linear fit ansatz according to the aforementioned leading order behaviour. Due to the observed curvature arising from the non-leading finite volume corrections only those data with $L_s \geq 16$ have been respected by the linear fit procedures. One finds that the intended infinite volume extrapolation can indeed reliably be performed thanks to the multitude of investigated lattice volumes reaching from $12^3 \times 32$ to $24^3 \times 32$ -lattices here.

The quality of the tuning procedure intending to hold the quark masses constant can then be examined in Fig. 2b displaying the results of the infinite volume extrapolation of $m_{t'}$. In the considered SM4 scenario the fluctuation of the quark mass has been constrained to roughly $m_{t'} = m_{b'} = 676 \pm 22 \text{ GeV}$. For later comparisons with the corresponding SM3 scenario we also present the analogous summary plot of our earlier investigations [3] of the latter setup where the degenerate quark masses have been fixed to approximately $m_t = m_b = 173 \pm 3 \text{ GeV}$ as demonstrated in Fig. 2a.

Figure 2: The infinite volume extrapolations of the degenerate quark masses observed in the lattice calculations specified in Tab. 1 are presented versus the cutoff parameter Λ . In the SM3 scenario (a) the fluctuation of the quark mass has been constrained to $m_t = m_b = 173 \pm 3 \text{ GeV}$, while $m_{t'} = m_{b'} = 676 \pm 22 \text{ GeV}$ is adjusted in the SM4 scenario (b).

The infinite volume results of the Higgs boson masses are finally presented in Fig. 3b. The numerical data for the upper mass bound have moreover been fitted with the analytically expected functional form of the cutoff dependence of the upper Higgs boson mass bound derived in Ref. [7]. It is given as

$$\frac{m_H^{up}}{a} = A_m \cdot [\log(\Lambda^2/\mu^2) + B_m]^{-1/2}, \quad (2.9)$$

with A_m, B_m denoting the free fit parameters and μ being an arbitrary scale, which we have chosen as $\mu = 1 \text{ TeV}$ here. One learns from this presentation that the obtained results are indeed in good agreement with the expected logarithmic decline of the upper Higgs boson mass bound with increasing cutoff parameter Λ .

The reader may want to compare these findings to the upper and lower Higgs boson mass bounds previously derived in the SM3. The lattice results corresponding to that setup have been determined in Ref. [3] and are summarized in Fig. 3a. The main finding is that especially the lower bound is drastically shifted towards larger values in the presence of the assumed mass-degenerate fourth quark doublet. From this analysis it can be concluded that the usually expected light Higgs boson seems to be incompatible with a very heavy fourth fermion generation.

Figure 3: Upper and lower Higgs boson mass bounds are shown for $N_c = 1$, $m_t = m_b = 173 \pm 3$ GeV (a) and $N_c = 1$, $m_{t'} = m_{b'} = 676 \pm 22$ GeV (b). Both upper bounds are each fitted with Eq. (2.9). The lower bound in (a) is also compared to a direct analytical computation depicted by the solid line as discussed in Ref. [3].

Acknowledgments

We thank George Hou and David Lin for ongoing discussions and M. Müller-Preussker for his continuous support. We moreover acknowledge the support of the DFG through the DFG-project *Mu932/4-2*. The numerical computations have been performed on the *HP XC4000 System* at the Scientific Supercomputing Center Karlsruhe and on the *SGI system HLRN-II* at the HLRN Supercomputing Service Berlin-Hannover.
