In the gauge/gravity duality, the deconfinement transition in the gauge theory is identified with the formation of a black hole in the dual gravity theory. By assuming this correspondence, many predictions on QGP have been made. In this talk, we justify this approach quantitatively, and also provide an intuitive way of understanding it. Firstly we give quantitative evidence for this identification from the thermodynamic study of the supersymmetric theory. We show that string theory and gauge theory give the same answer, even at finite temperature, including the $1/N$ correction. Then we consider generic gauge theories and show that the deconfinement transition is the condensation of very long and self-intersecting QCD strings, which is analogous to the formation of a black hole in string theory.

*Speaker.
1. Introduction

In the gauge/gravity duality conjecture [3], the deconfinement phase of the gauge theory is dual to a black hole geometry in the gravity side [2]. In the first part of this talk, we give quantitative evidence for this identification, by solving a concrete example in both gauge and gravity sides, at the level of the string theory (i.e. finite $\alpha'$ and finite $g_s$). In the second part, we give an intuitive way of understanding this correspondence, without referring to a sophisticated dictionary of the duality. Our argument does not assume the dual gravity description, and hence it is applicable to generic gauge theories including QCD.

2. Quantitative test of the gauge/gravity duality

Let us consider the $U(N)$ maximally supersymmetric Yang-Mills theory in flat $(p+1)$-dimensional spacetime ($p = 0, 1, 2$ and $3$), whose action is given by

$$S = \frac{1}{g_{YM}^2} \int d^{p+1}x \text{Tr} \left\{ \frac{1}{4} F_{\mu\nu}^2 + \frac{1}{2} (D_\mu X_i)^2 - \frac{1}{4} [X_i, X_j]^2 \right\} + (\text{fermions}), \quad (2.1)$$

where $\mu, \nu$ run from 1 to $p+1$ and $X_i$ ($i = 1, 2, \cdots, 9-p$) are scalar fields. In [3], it has been conjectured that this theory is in the deconfining phase at any nonzero temperature, in the sense that the Polyakov loop has nonzero expectation value, and that it describes full string dynamics around the black $p$-brane. Near the horizon, the metric of the black $p$-brane geometry is given by

$$ds^2 = \alpha' \left\{ \frac{U^{(7-p)/2}}{g_{YM}\sqrt{d_pN}} \left[ - \left( 1 - \frac{U_0^{7-p}}{U^{7-p}} \right) dt^2 + dy_{\parallel}^2 \right] ight.$$ \[ + \frac{g_{YM}\sqrt{d_pN}}{U^{(7-p)/2}} \left( 1 - \frac{U_0^{7-p}}{U^{7-p}} \right) dU^2 + g_{YM}\sqrt{d_pN} U^{(p-3)/2} dΩ_{8-p}^2 \right\}, \quad (2.2)

where the Yang-Mills coupling $g_{YM}$ and the size of the gauge group $N$ in the corresponding super Yang-Mills theory are used. A constant $\alpha'$ is the square of the string length, $(t, y_{\parallel})$ represent the $(p+1)$-dimensional extension of the brane, $U$ and $Ω$ are the radial and angular coordinate of the transverse directions, and $U_0$ is the place of the horizon. The Hawking temperature is

$$T_H = \frac{(7-p)U_0^{(5-p)/2}}{4\pi \sqrt{d_p g_{YM}^2 N}}, \quad (2.3)$$

where $d_p = 2^{7-2p} \pi^{(9-3p)/2} \Gamma((7-p)/2)$. The string coupling constant is given by

$$g_s = (2\pi)^{2-p} g_{YM}^2 \left( \frac{d_p g_{YM}^2 N}{U^{7-p}} \right)^{\frac{1-p}{4}}. \quad (2.4)$$

When $\lambda = g_{YM}^2 N$ is fixed, it behaves as $g_s \propto 1/N$, in the same way as in 't Hooft’s identification. The Hawking temperature and the mass of the black brane are identified with the temperature and the energy $E = -\partial \log Z/\partial \beta$ of the gauge theory, where $Z$ is the partition function.
Deconfinement transition as a black hole formation

In this work we study the case of $p = 0$. The gauge theory is quantum mechanics of $N \times N$ matrices, which was originally proposed as the matrix model of M-theory [3]. It can be studied extensively by using the Monte Carlo method. In the gravity side, the black hole mass can be calculated by adding stringy corrections to the black 0-brane geometry shown above. The result is [5]

$$\frac{1}{N^2} E_{\text{gravity}} = (7.41 T^{2.8} + a T^{4.6} + \cdots) + (-5.77 T^{0.4} + b T^{2.2} + \cdots) \frac{1}{N^2} + O \left( \frac{1}{N^4} \right), \quad (2.5)$$

where $T = \lambda^{-1/3} T_H$ is dimensionless effective temperature and $a, b$ are unknown constants. The energy $E_{\text{gravity}}$ is also made dimensionless, by multiplying $\lambda^{-1/3}$. In the following, we simply set $\lambda = 1$ without loss of generality. Higher order terms in each power of $1/N$ represent to the $\alpha'$ corrections, which appear because strings are not point-like. If the gauge/gravity duality conjecture is correct, this expression must be reproduced from the matrix quantum mechanics.

The $O(N^0)$ terms of the dual gravity prediction (2.5) have been tested previously. In particular, the $\alpha'$ correction $a T^{4.6}$ has been confirmed with $a = -5.58(1)$, by looking at $T \gtrsim 0.5$ [6].

In order to study the $1/N$ correction, we must study rather small values of $N$. Here we study $N = 3, 4$ and 5. (That we have to take $N$ small caused a technical problem which required a proper treatment; see [2].) We also have to study low temperature where the $\alpha'$ correction becomes small, because there are too many fitting parameters otherwise. At $0.08 \leq T \leq 0.11$, we estimated the coefficient of $1/N^2$ by using a fitting ansatz $E_{\text{gauge}} = 7.41 T^{2.8} + c_1(T)/N^2 + c_2(T)/N^4$ for each fixed value of $T$. We confirmed that $c_1(T)$ is consistent with $-5.77T^{0.4}$; see Fig.2, in which this coefficient normalized by the dual gravity prediction, $c_1/(-5.77T^{0.4})$, is plotted. It is reasonably close to 1. This is very strong evidence that the gauge/gravity duality holds at quantum gravity level, at least at the 1-loop level.

3. Why the deconfinement phase describes the black hole

Motivated by the numerical confirmation in Sec.3, in this section we give an intuitive expla-
Deconfinement transition as a black hole formation

Masanori Hanada

Figure 2: The confining phase is the gas of free strings (left). As the system is heated up, it becomes denser (middle), the interaction becomes non-negligible and a long string is formed (right). This is analogous to the formation of a black hole in string theory. [3].

When we identify the long string with a black hole, fluctuations of the string near the horizon are regarded as open strings attached to black hole (Fig. 3). In terms of the gauge theory, these open strings are open Wilson lines which have $N$ color degrees of freedom at their endpoints. Therefore, we can interpret that the black hole is made from $N$ D-branes.

In the Euclidean theory, the deconfinement is characterized by the condensation of the Polyakov loop, which can naturally be related to the black hole geometry in the gravity dual [2]. This can be explained from our picture as follows. First notice that the condensation of the Polyakov loop is
equivalent to the disappearance of the linear confinement potential between a pair of probe quark and anti-quark. In terms of strings, the linear potential in the confining phase appears because an open string connecting probes must be stretched as they are separated. In the deconfining phase, however, as soon as a short open string is introduced, it intersects with closed strings many times, and they immediately interact at one of the intersections to form a long open string (Fig. 4). Therefore, probes can be separated without stretching the open string, or equivalently, without costing energy.

In order to test this picture, we have analytically estimated the deconfinement temperature of the strong-coupling lattice gauge theory with $D$-dimensional spatial lattice and continuum time [12], and compared it with numerical simulation. Because the thermal transition in this model is of first order, we compared the analytically predicted critical temperature with the temperature region where the hysteresis of the expectation value of the Polyakov line is observed. The result is shown in Fig. 5. The vertical axis is $T/\lambda$, where $\lambda$ is the 't Hooft coupling, and the vertical axis is the spatial dimension $D$. The analytic prediction, $(T_c / \lambda) = 1 / (2 \log(2D - 1))$, is shown by the dashed line. We can see $T_c$ is inside the hysteresis, which supports the validity of the analytic prediction and hence the long-string description of the deconfinement phase.

4. Conclusion

In the first part of this talk we have provided the first quantitative evidence for the gauge/gravity duality at finite temperature and finite-$N$. It means now lattice gauge theorists can study quantum gravity by studying the gauge theory. Motivated by this numerical confirmation, we proceeded to

Figure 5: The temperature range of the hystereses of the Eguchi-Kawai model. The dashed line is the analytic prediction for the critical temperature, $(T_c/\lambda) = 1/(2\log(2D-1))$. $N = 64, n_f = 16$.

an intuitive way of understanding the duality in terms of QCD-strings. In the gauge theories with dual gravity descriptions, the condensation of the Wilson loops argued in this paper is equivalent to the condensation of fundamental strings and formation of an actual black hole. By following the time evolution of the loops, it should be possible to see how a black hole forms and thermalizes. As we have seen, qualitative features are common even in the strong coupling limit of simple matrix models, and hence they should serve as good toy models for a black hole. We believe that close collaboration between lattice gauge theorists and string theorists will be the key to the understanding of quantum gravity.
