Spectral triples and Toeplitz operators

Kevin Falk

We present the main results of [6] on the construction of spectral triples using the algebra generated by Toeplitz operators acting on Fock spaces and Hardy and Bergman spaces over a strictly pseudoconvex domain of $\mathbb{C}^n$. Different Dirac operators are proposed and we compare their influence on the dimension of the corresponding spectral triple. Since Toeplitz operators play an important role in deformation quantization, we also study how Berezin–Toeplitz quantization can be incorporated in the framework of noncommutative geometry.
1. A quick overview of noncommutative geometry

The field of noncommutative geometry (NCG) gives a mathematical framework to describe geometric entities with algebraic tools. The starting result of NCG is the Gelfand–Naimark theorem \[8\], which states a commutative C*-algebra, unital or not, is isometrically *–isomorphic to \(C_0(X)\), the set of continuous functions vanishing at infinity on some locally compact Hausdorff space \(X\). Conversely, given \(X\), then \(C_0(X)\) is trivially commutative. Roughly speaking, it means that geometric spaces can be entirely characterized as a commutative algebra.

Connes’ idea \[4\] was to consider not commutative algebras anymore but rather noncommutative ones, and study the corresponding “noncommutative space”. From a physicist’s standpoint, NCG has natural applications in quantum mechanics, in which observables do not commute.

The main geometric information are encoded in the principal object of NCG, a spectral triple \((\mathcal{A}, \mathcal{H}, D)\), consisting in

- an involutive algebra \(\mathcal{A}\),
- a faithful representation \(\pi\) of \(\mathcal{A}\) by bounded operators on a Hilbert space \(\mathcal{H}\),
- a selfadjoint operator \(D\) acting on \(\mathcal{H}\) such that for any \(a \in \mathcal{A}\), the extended operator of \([D, \pi(a)]\) is bounded, and \(\pi(a)(1 + D^2)^{-1/2}\) is compact.

Also, the notion of dimension is given by the quantity \(\inf\{s \in \mathbb{R}, \text{Tr}(|D|^{-s}) < +\infty\}\).

We are interested in our case in algebras related to the so-called Toeplitz operators acting on Hilbert spaces of holomorphic functions over strictly pseudoconvex manifolds in \(\mathbb{C}^n\) or \(\mathbb{C}\) itself.

2. Deformation quantization and Toeplitz operators

Geometric quantization \[5\] describes relations between classical and quantum mechanics by studying geometric aspects of a dynamical system. In this context, symplectic manifolds play the role of phase spaces of the system and holomorphic sections represent classic observables. Later on, deformation quantization (DQ) \[1\] emerged to avoid some technical drawbacks of the geometric quantization. Mimicking the Weyl quantization \[7\] on flat phase spaces, DQ constructs a formal associative noncommutative star product \(*_h\) on the Poisson algebra \((\mathcal{C}^\infty(\Omega), \{., .\})\) of classical observables over some symplectic phase space \(\Omega\), such that, in a suitable sense

\[ f *_h g = \sum_{j \in \mathbb{N}} h^j C_j(f,g), \quad \text{as } h \to 0, \]

where the bilinear operators \(C_j\) verify

\[ C_0(f,g) = fg, \quad C_1(f,g) - C_1(g,f) = -\frac{i}{2\pi} \{f, g\}, \quad C_j(f,1) = C_j(1,f) = 0 \forall j \in \mathbb{N}. \]

In this context, Toeplitz operators allow to construct the so-called Berezin–Toeplitz star product \[3\] for phase spaces modeled by pseudoconvex domains.

We consider an open smoothly bounded strictly pseudoconvex manifold \(\Omega \subset \mathbb{C}^n\) and fix a defining function \(r\), i.e. verifying \(r|_\Omega > 0\), \(r|_{\partial \Omega} = 0\) and \(\partial r|_{\partial \Omega} \neq 0\). Three Hilbert spaces will be used:

- Hardy space \(H^2\): the set of boundary values of holomorphic functions on \(\Omega\).
• Bergman space $A^2_m$: holomorphic functions in $L^2(\Omega, w(z)dz)$, with a weight of the form $w = r^m g$, $0 < g \in C^\infty(\Omega)$, $m > -1$.
• Fock space $F_p$: holomorphic functions in $L^2(\mathbb{C}^n, \rho(z)e^{-|z|^2}dz)$, with $0 < \rho \in C^\infty(\mathbb{C}^n)$.

An interesting property we will use later on is that there are unitaries between $L^2(\mathbb{R}^n)$ and all these Hilbert spaces (moreover we have explicit formulas when $\Omega = \mathbb{B}^n$ is the unit ball of $\mathbb{C}^n$).

A usual Toeplitz operator on $H^2$ is of the form $T_u : v \in H^2 \mapsto \Pi(uv) \in H^2$, with $u \in C^\infty(\partial \Omega)$ (Toeplitz on the Bergman and Fock spaces are defined similarly). Toeplitz have properties ($u \mapsto T_u$ is linear, $T_u^* = T_u$, $\|T_u\| \leq \|u\|_\infty$, etc.) that are interesting in both NGC and DQ, but one of the main difficulties is that they do not form an algebra since in general $T_u T_v \neq T_{uv}$.

Boutet de Monvel and Guillemin extended Toeplitz operators to Generalized Toeplitz operators (GTOs) [2], that is, operators of the form $T_Q : u \in H^2 \mapsto \Pi(Qu) \in H^2$, where $Q$ is a pseudodifferential operator ($\Psi$DO) on $\partial \Omega$. The GTOs enjoy useful properties which allow us to build spectral triples. The following table gives the principal ones:

<table>
<thead>
<tr>
<th>Properties</th>
<th>Interests for NCG</th>
</tr>
</thead>
<tbody>
<tr>
<td>The set of all GTOs form a filtered algebra</td>
<td>Good candidate for $\mathcal{A}$</td>
</tr>
<tr>
<td>Locally, $GTO(\partial \Omega) \approx \Psi DO(\mathbb{R}^n)$ mod smoothings</td>
<td>Links with known spectral triples</td>
</tr>
<tr>
<td>$\forall T_\Omega, \exists P$ s.t. $\text{ord}(Q) = \text{ord}(P)$, $T_\Omega = T_P$ and $[\Pi, P] = 0$</td>
<td>Control the axioms of a spectral triple</td>
</tr>
<tr>
<td>Existence of a principal symbol: $\sigma(T_\Omega) := \sigma(Q)</td>
<td>_\Sigma$</td>
</tr>
<tr>
<td>Dixmier trace: $\text{Tr}<em>{\partial \Omega} T</em>\Omega = \frac{1}{\pi^{\frac{\dim \partial \Omega}{2}}} \int_{\partial \Omega} \sigma(T_\Omega)(x, \eta_\kappa)$</td>
<td>Computation of the dimension</td>
</tr>
</tbody>
</table>

*(*) given a contact form $\eta$ on $\partial \Omega$, $\Sigma := \{(x, t\eta_\kappa) \in T^* \partial \Omega, t > 0\}$.

3. Examples of spectral triples

Let us describe now different spectral triples involving algebras generated by the Toeplitz operators of different kinds. The principal example of spectral triple over $\partial \Omega$ is the following:

• $\mathcal{A}$: the set of GTOs of order $\leq 0$,
• $\mathcal{H} = H^2(\partial \Omega)$,
• $\mathcal{D}$: an elliptic selfadjoint GTO of order 1,

form a spectral triple of dimension $n = \dim \partial \Omega$. The main steps to prove this are the following: $\mathcal{A}$ is trivially an involutive algebra with representation the identity on $\mathcal{H}$, $\mathcal{D}$ is elliptic with $\mathcal{D}^{-1} \in GTO^{-1}$ hence has compact resolvent, for any $T_P \in \mathcal{A}$, $[\mathcal{D}, T_P] \in GTO^0$ so is bounded, and finally the Weyl formula for GTOs leads us to the dimension.

To take an example of Dirac operator in the case $\Omega = \mathbb{B}^n$, we can use the usual Dirac on $\mathbb{R}^n$ ($\mathcal{D} = \nabla^2 \hat{\rho}$) transported on $H^2$ via the known unitaries. We then obtain a spectral triple of dimension $2n = \dim \partial \Omega$. This difference in the dimension comes from the fact that a $\Psi$DO of order $k$ on $\mathbb{R}^n$ is transformed to a GTO of order $k/2$.

The next spectral triple concerns the domain $\Omega$ itself:

• $\mathcal{A}$: the algebra generated by Toeplitz operators $T_f, f \in C^\infty(\overline{\Omega})$,
• $\mathcal{H}$: the weighted Bergman space $A^2_m$, 

3
On the Fock space on $\mathbb{C}$, we have the spectral triple of dimension $2\dim \mathbb{R} \mathbb{C}$, formed by
- $\mathcal{A} = \{ T_f, f \in \cup_{s \leq 0} E^s \}$, where $E^s$ is the set of functions on $\mathbb{C}$ verifying $f(z) \sim |z|^s \sum_{k=0}^{\infty} f_k \frac{1}{|z|^k}$ as $|z| \rightarrow \infty$, with $s \in \mathbb{R}$ and $f_k$ smooth on $S^1$,
- $\mathcal{H} = F_\rho$,
- $\mathcal{D} = T_g$, $g \in E^1$ and measurable,

The proof uses some relations between Toeplitz on Fock spaces and Weyl operators on $\mathbb{R}^2$ (which enjoys properties similar to $\Psi$DOs).

Finally, let us describe a spectral triple obtained from the Berezin–Toeplitz quantization. It can be shown that GTOs can also be defined on the Hardy space $\tilde{H}^2$ over $\partial \tilde{\Omega}$, where $\tilde{\Omega}$ is a disk bundle of $\Omega$. It happens that $\Lambda = K^* K$ is an elliptic selfadjoint pseudodifferential operator on $L^2(\partial \tilde{\Omega})$ of order -1, where $K$ is the Poisson extension operator. From the fact that the spaces $\tilde{H}^2$ and $\bigoplus_{m \in \mathbb{N}} A_m^2(\Omega)$ are unitarily equivalent, we get the following result:
- $\mathcal{A}$: the algebra generated by the Toeplitz of the form $T_f^\oplus = \bigoplus_{m \in \mathbb{N}} (T_f on A_m^2(\Omega))$,
- $\mathcal{H} = \bigoplus_{m \in \mathbb{N}} A_m^2(\Omega)$,
- $\mathcal{D}$, the operator on $\mathcal{H}$ corresponding to $T_{\Lambda}^{-1}$ via the mentioned unitary,

form a spectral triple of dimension $n + 1$. To prove this, we use the result of Berezin–Toeplitz quantization about the existence of a start product $\star$ such that $T_{f_1}^\oplus T_{g_1}^\oplus m \rightarrow \infty \sim T_{f_1 \star g_1}^\oplus$.
