The Ultra-Fast Flash Observatory pathfinder (UFFO-p) is a new space mission dedicated to detect Gamma-Ray Bursts (GRBs) and rapidly follow their afterglows in order to provide early optical/ultraviolet measurements. A GRB location is determined in a few seconds by the UFFO Burst Alert & Trigger telescope (UBAT) employing the coded mask imaging technique and the detector combination of Yttrium Oxyorthosilicate (YSO) scintillating crystals and multi-anode photomultiplier tubes. The results of the laboratory tests of UBAT's functionality and performance are described in this article. The detector setting, the pixel-to-pixel response to X-rays of different energies, the imaging capability for  $< 50$  keV X-rays, the localization accuracy measurements, and the combined test with the Block for X-ray and Gamma-Radiation Detection (BDRG) scintillator detector to check the efficiency of UBAT are all described. The UBAT instrument has been assembled and integrated with other equipment on UFFO-p and should be launched on board the Lomonosov satellite in late-2015.

## 1. Introduction and Description of UBAT

The Ultra-Fast Flash Observatory pathfinder (UFFO-p) [1, 2, 3] is a new space mission dedicated to detect Gamma-Ray Bursts (GRBs) and rapidly follow their afterglows to provide early optical/ultraviolet measurements. It consists of two scientific instruments. One is the UFFO Burst Alert & Trigger telescope (UBAT) [4, 5, 6] which employs the coded mask technique providing X-ray/gamma-ray imaging observations in the energy range of 10 – 150 keV with half-coded field of view (FOV)  $70.4^\circ \times 70.4^\circ$  and angular resolution  $\leq 10'$ . The second instrument is the Slewing Mirror Telescope (SMT) [7, 8] with the field of view of  $17' \times 17'$  and optical/ultraviolet range of 200 – 650 nm. It consists of a Ritchey-Chrétien telescope with an Intensified Charge-Coupled Device in its focal plane together with a plane slewing mirror. In this article the laboratory tests of UBAT flight module (FM) (Figure 1) are briefly described. UBAT and SMT have been assembled and integrated with the control electronics on UFFO-p which is planned to be launched on the Lomonosov Moscow State University satellite [9].

UBAT is a wide-field X-ray imager which provides triggers of GRBs and determines their location via the coded mask technique. It consists of a coded mask, hopper, detector, and readout electronics. The coded mask is a 1 mm thick plate of tungsten with a random pattern of  $68 \times 68$  opened and closed tiles, having 44.5 % of open area. The size of each tile is  $5.76 \text{ mm} \times 5.76 \text{ mm}$ , i.e. double the detector pixels size. It is placed 280 mm above the detector surface and it casts a mosaic shadow onto the detector. From the cross-correlation of the position of the projected shadow and the coded mask pattern one can determine the direction of the X-ray source [10]. The hopper supports the coded mask and provides shielding against the diffuse cosmic X-ray background. It is made of 2 mm thick aluminium with 0.1 mm thick layer of tungsten. The detector comprises a Cesium-doped Yttrium Oxyorthosilicate (YSO) ( $\text{Y}_2\text{SiO}_5 : 0.2\% \text{ Ce}$ ) scintillator crystal array and Hamamatsu *R11265-03-M64* Multi-Anode Photomultiplier Tubes (MAPMTs), together with the analogue and digital electronics. There are 36 MAPMTs and each of them has  $8 \times 8 = 64$  channels, thus providing 2304 imaging pixels in total. On the top of each MAPMT there is a

**Figure 2:** *Left:* The UBAT FM detector response to X-rays of energies  $\leq 50$  keV is shown. The color scale indicates the total number of counts in each pixel. White color means zero counts at noisy detector pixels, which have been disabled noisy. *Right:* The expected normalized spectrum given by the radiation produced by the X-ray tube illuminating the detector after attenuation in the air and in the Cu filter is displayed.

$8 \times 8$  YSO crystal array. The volume of each single crystal is  $2.68$  (length)  $\times$   $2.68$  (width)  $\times$   $3.0$  (height)  $\text{mm}^3$ .

## 2. Pixel-to-Pixel Response

For the best imaging performance a uniform response of the detector is required because the imaging algorithm effectively subtracts any uniform background. In order to test the pixel-to-pixel response, to set the thresholds for each MAPMT and to determine the noisy pixels an X-ray tube was placed on axis in front of the detector without the coded mask attached. A tube with adjustable current and voltage of the accelerated electrons was used. It produced a broadband Bremsstrahlung X-ray radiation up to 50 keV. Figure 2 shows results for the following setup: source-detector distance of 8088 mm, tube voltage (current) of 50 kV ( $5.3 \mu\text{A}$ ), total exposure time of 186 s and with a 1.6 mm thick Cu filter placed in front of the tube to attenuate the flux.

The recorded data were processed off-line with analysis software which used a geometrical center hit-finder to eliminate the optical crosstalk caused by total reflections at the glass-vacuum (photo-cathode) interface [6]. There were 30 460 registered counts due to the background and 137 256 counts due to the source, and the area of the enabled detector pixels was  $160.2 \text{ cm}^2$  thus giving a count rate due to the source of  $4.6 \text{ cnt s}^{-1} \text{ cm}^{-2}$ . Figure 2 shows the expected count spectrum given by the radiation produced by the X-ray tube after attenuation in the air and in the 1.6 mm thick Cu filter. It was calculated from the measured X-ray spectrum given by the tube's manufacturer and considering the attenuation law.

## 3. Test of Imaging

The results of imaging with X-rays of energies  $\leq 50$  keV are shown in Figure 3. The X-ray tube was placed on the axis of UBAT with voltage (current) set to 50 kV ( $5.3 \mu\text{A}$ ). The source-

**Figure 3:** *Left:* Reconstructed X-ray image as an SNR map. Color scale corresponds to the SNR value. The X-ray tube was placed on axis with voltage 50 kV. The X-ray source is clearly visible in the middle of the FOV. *Right:* The image peak SNR evolution during the exposure time.

detector distance was 8 090 mm and a 1.8 mm thick Cu filter was used to additionally attenuate the flux. For the image reconstruction a conical beam algorithm was used because at this distance the beam illuminating the coded mask does not have exactly parallel rays, but they diverge at an angle of about  $\pm 0.6^\circ$ .

Data were processed off-line with analysis software where an FM hit-finder (the same concept as implemented in the UFFO-p electronics) was applied on each 10 ms data frame in order to reduce the crosstalk and increase the peak signal-to-noise ratio (SNR) in the reconstructed image. The FM hit-finder utilizes a hit pattern recognition technique. The total exposure was 31 s. The coded mask was attached and it has an open area fraction of about 0.445. There were 4 026 registered counts due to the background and 4 781 counts due to the source, and the area of enabled detector pixels was  $154.6 \text{ cm}^2$  thus giving a count rate due to the source under the open mask pixels of  $2.2 \text{ cnt s}^{-1} \text{ cm}^{-2}$ .

#### 4. Angular Resolution

The X-ray source was placed in a fixed direction, on axis, and the recorded data of one exposure totalling 30 s were split into 15 independent sub-samples each of duration 2 s. The imaging algorithm for each sub-sample was run separately. The variance of the calculated directions of the source indicates the angular resolution (Figure 4). The image reconstruction algorithm was run for three different thresholds of  $\text{SNR}_{\text{thr}} = 5, 7, 9$  at which the algorithm was forced to stop. This allows comparison of the dependence of the localization accuracy on SNR. The experimental setup was the same as in the previous section except that here a 1.6 mm thick Cu filter was used. The count rate due to the source beneath the open mask pixels was  $4.1 \text{ cnt s}^{-1} \text{ cm}^{-2}$ .

For the detection of  $\text{SNR} = 5.0 \sim 5.6$  the standard deviations of the calculated positions in the x-axis and y-axis were  $\sigma_X = 8.2'$  and  $\sigma_Y = 10.3'$ . For  $\text{SNR} = 7.0 \sim 7.4$  they were  $\sigma_X = 6.5'$  and  $\sigma_Y = 6.4'$ . For  $\text{SNR} = 8.6 \sim 9.4$  they were  $\sigma_X = 5.1'$  and  $\sigma_Y = 6.7'$ . Considering that the angular radius of the source was  $1'$ , the result is close to the designed resolution of  $\pm 5'$  for  $> 7\sigma$  detection.

**Figure 4:** The angular resolution of UBAT FM for different detection thresholds is shown. The variance of the measured source positions of 15 different exposures indicate the resolution. SMT has FOV=  $17' \times 17'$ .

## 5. Combined Test with BDRG Detector

The UBAT FM detector was also tested together with the laboratory version of the Block for X-ray and Gamma-Radiation Detection (BDRG) [11] scintillator gamma-ray spectrometer. BDRG will be one of the instruments on the Lomonosov satellite. It consists of 75 mm (diameter)  $\times$  3 mm (thickness) NaI(Tl) scintillator optically coupled with 80 mm (diameter)  $\times$  17 mm (thickness) CsI(Tl). Both crystals are attached to the same photomultiplier tube. The efficiency in the range 30 – 100 keV is close to 100 %.

The X-ray tube was set to 50 kV, 5.3  $\mu$ A, a 1.6 mm thick Cu filter was placed in front of the tube and the source-detector distance was 7760 mm. The measured background rate by BDRG in the range 10 – 100 keV was  $0.15 \text{ cnt s}^{-1} \text{ cm}^{-2}$  and the rate due to the source at energy  $>30$  keV was  $5.18 \text{ cnt s}^{-1} \text{ cm}^{-2}$ . This count rate can be compared with the measurement done with UBAT FM for the same setup as described in the previous section. However, in that case the source-detector distance was 8090 mm. The count rate due to the source and under the open mask pixels was  $4.10 \text{ cnt s}^{-1} \text{ cm}^{-2}$ . Taking into account this distance difference the expected count rate detected by UBAT at distance 7760 mm would be  $\approx 4.46 \text{ cnt s}^{-1} \text{ cm}^{-2}$ . Comparing this with the count rate from BDRG one can infer the efficiency of UBAT FM at the range of 30 – 50 keV to be  $4.46/5.18 = 86\%$ .
