In the search for a realistic walking technicolor model, QCD with many flavors is an attractive candidate. From the series of studies by the LatKMI collaboration, we present updated results of the scaling properties of various hadron spectra, including the (pseudo)scalar, vector, and baryon channels, for \(N_f = 8\) QCD analyzed with the HISQ action. By comparing these with \(N_f = 12\) QCD, which has properties consistent with conformality, possible signals of walking dynamics are discussed. We also present a preliminary result of the flavor-singlet pseudoscalar mass in many-flavor QCD.

Walking and conformal dynamics in many-flavor QCD

Hiroshi Ohki

1. Introduction

SU(3) gauge theory with many flavors is a very good candidate for a walking technicolor model. The LatKMI collaboration has been systematically investigating the SU(3) gauge theory with \( N_f \) fundamental fermions with \( N_f = (0), 4, 8, 12, \) and 16 using a common setup of the lattice action. We utilize the Highly improved staggered quark (HISQ) action with tree-level Symanzik gauge action (HISQ/tree). Our previous results suggested that \( N_f = 8 \) QCD could have a walking behavior \([1]\). Similar results were also given in \([2]\). More interestingly, the flavor-singlet scalar mass is found to be as light as the Nambu-Goldstone (NG) pion (\( \pi \)) in \( N_f = 8 \) QCD \([3]\). In this proceeding, we present our updated results of the scaling properties of various hadron spectra, including the pseudoscalar mass (\( M_\pi \)), decay constant (\( F_\pi \)), vector mass (\( M_\rho \)), and nucleon mass (\( M_N \)) in comparison with \( N_f = 12 \) QCD. We also present a new result of the measurement of the flavor-singlet pseudoscalar (\( h' \)) mass for the first time in the many flavor QCD. The mass of \( h' \) meson is interesting, since the fermion loop contribution, which would naturally enhance as \( N_f \) increases, plays an essential role. Using a topological charge density operator and the gradient flow we can obtain a good signal for the \( h' \) meson two-point function. All the updated results shown here are preliminary.

2. Simulation setup and simple analysis

We have been generating configurations at \( \beta = 3.8 \) with lattice volumes \((L, T) = (18, 24), (24, 32), (30, 40), (36, 48) \) and \((42, 56)\), for various fermion masses. Compared to our previous results in Ref. \([1]\), we have added new simulation points in the smaller mass region of \( m_f = 0.012 \) and 0.015 on \( L = 42 \) with 2,200 and 4,760 HMC trajectories, and accumulated more configurations at smaller masses on larger volumes. We have now typically ten times many trajectories than the previous data for smaller mass region. The details of simulation parameters and updated results can be found in Ref. \([3]\), where we should mention that some spectrum data have been changed at the 1 \( \sigma \) level from the previous results. This is due to the fact that there are unexpectedly long auto correlation lengths for HMC history, which appeared also in the topological history presented in Ref. \([5]\). In the present analysis, taking a longer HMC trajectory with smaller fermion masses, we obtain more reliable results, which enable us to deeply investigate the scaling behavior of the various hadron spectra. As shown later, this improvement has affected the numerical result for the finite-size hyperscaling analysis, while the statement that there exists an (approximate) conformal behavior is unchanged.

As a simple analysis, we study dimension-less ratios of the physical quantities as \( M_\rho / M_\pi \), \( F_\pi / M_\pi \), and \( M_N / M_\pi \) as a function of \( M_\pi \) shown in Fig. \([1]\). Those ratios are increasing towards the chiral limit. A similar tendency can be seen in our \( N_f = 4 \) data, and is clearly different from the one in \( N_f = 12 \), where we find those ratios have mild \( M_\pi \) dependence, and become a constant in the small-\( M_\pi \) region. As for the ratio analysis, our updated result is consistent with the previous result.

3. Hyperscaling analysis

Although the ratio analysis shows a consistent behavior with the theory having broken chiral symmetry, we can still expect some remnant of the conformal symmetry, if the theory is near the

Figure 1: $F_\pi/M_\pi$ vs. $M_\pi$ (Left), $M_\rho/M_\pi$ vs. $M_\pi$ (Center), and $M_N/M_\pi$ vs. $M_\pi$ (Right) for $N_f = 8$.

edge of the conformal window. In fact, in our previous data we have found that each quantity has an approximate hyperscaling in the intermediate mass region. As shown below, using the updated result with smaller fermion masses, it turns out that this scaling can be seen even at smaller fermion masses. This is one major change in our updated result.

We carry out an individual finite-size hyperscaling fit using a naive function,

$$\xi_h = c_0 + c_1 x,$$

(3.1)

where $\xi_h = LM_h$, $h = \pi, \rho, \text{and } N$, or $\xi_F = LF_\pi$, and $x = Lm^{1/(1+\gamma)}$. In the finite-size hyperscaling analysis we only use the updated data that covers a simulation parameter region with $0.012 < m_f < 0.08$ and $24 \leq L \leq 42$.

The fit results are shown in Fig. 2 and Table 1. Unlike the previous result (c.f. Table V in Ref. [1]), the naive fit works even in a region of smaller masses except for $M_\pi$. The resulting value of $\gamma$ is $O(1)$, but it is not universal.

From the mass-deformed conformal theory point of view, non-universality and a large $c_2$ might be caused by corrections to hyperscaling. To test such a possibility, we carry out a finite-size hyperscaling with mass corrections. Among various types of the mass corrections, we adopt a renormalization group inspired correction term [6] as a benchmark test, which is

$$\frac{\xi_h}{1 + c_2 m^{\omega}} = c_0 + c_1 x.$$

(3.2)

In this formula, there is another exponent $\omega$ in the correction term, whose theoretical origin comes down to the critical exponent of the irrelevant operator $g$ (gauge coupling) in the vicinity of the infrared fixed point. As $\omega$ can not be analytically determined in the present analysis, we treat it as a fit parameter. Then we carry out the simultaneous finite-size hyperscaling fit for the quantities

of $F_\pi$, $M_\pi$, $M_\rho$, and $M_N$ with common values of $\gamma$ and $\omega$. As a comparison we also perform a simultaneous fit without a correction (Eq. [3.1]). Both results are shown in Fig. 3, where the vertical axis $y$ in the $x$-$y$ plane means,

$$y = \frac{(c_0 - c_1)/c_1}{x},$$  

(naive fit),

$$y = \frac{(c_0/1 + c_2 m^0) - c_0}{x}$$

(with correction).

The data are distributed around the fit line, i.e. $y = 1$, where the fitted data with mass correction are closer to the fit line than the naive one. The fit results are tabulated in Table 2. As a result, the mass correction term improves the fit accuracy and we obtain a reasonable $\chi^2$/dof and $\gamma \sim 1$.

However, we should note that in this approach there is no systematic way to incorporate finite mass and volume corrections to the universal hyperscaling relation, and the value of $\gamma$ depends on the model in general. In addition, the contribution of the correction term for $M_\pi$ is found to be comparable to that of the naive hyperscaling term in the simulation mass region. Note that $c_2$ differs depending on the quantity. In this situation, it is not immediately obvious whether each data actually shows a universal scaling towards the chiral limit. (As shown later, there is a clear difference in the correction between $N_f = 8$ and 12.) Even if this is the case, $\gamma(M_\pi) \sim 1$ is also consistent with the chiral broken phase, since it coincides with the leading order of $m_f$ dependence of $M_\pi$ in the chiral perturbation theory (ChPT) formula \(^2\). In either case whether $N_f = 8$ QCD is in the conformal phase with $\gamma \sim 1$ or in the chirally broken phase, we can expect that $M_\pi$ behaves like $M_\pi \sim m_f^{1/2}$ as approaching the chiral limit.

In the next section, in order to see such a scaling behavior, we study mass (scale) dependence of $\gamma$ for each quantity in detail.

4. Prospect towards the chiral limit

To see a scaling property in detail, we need to systematically study the fermion mass dependence of $\gamma$. We consider a window for the fermion mass parameter which corresponds to a range

\[^2\text{In fact, a ChPT-like fit also works in our data, where we can obtain a tiny non-zero } F_\pi \text{ in the chiral limit, and the higher order term for } M_\pi^2 \text{ is required to fit the data} \]
for three sequential fermion masses, and slide it from $[m_f^\text{min}, m_f^\text{max}] = [0.012, 0.02]$ to $[0.07, 0.1]$. We
then perform a fit for each window. The data on the largest volume are used for each mass, so that
we use the naive hyperscaling function $M_b \propto m_f^{1/(1+\eta)}$. An effective mass anomalous dimension
(denoted $\gamma_{\text{eff}}(m_f)$) is calculated as a fit result for each window.

The result for $\gamma_{\text{eff}}(m_f)$ is plotted in the left panel of Fig. 4, where the $x$-axis means the central
value of the fit range. We find that the value of $\gamma_{\text{eff}}$ for $M_\pi$ increases and it looks like approaching
$\sim 1$. While our data are far away from the chiral limit, this tendency could be a promising signal
for the chirally broken phase. In fact, this result is in sharp contrast to the $N_f = 12$ result, which is
shown in the right panel of Fig. 4. In $N_f = 12$, $\gamma_{\text{eff}}$ for $M_\pi$ never increases towards the chiral limit.
Furthermore, $\gamma_{\text{eff}}$ from various quantities tend to become universal in a range of small mass within
our statistical accuracy, indicating that the system is in the scaling region. This is consistent with
the conformal nature for $N_f = 12$ QCD. A large correction to $M_\pi$ for $N_f = 8$ found in the previous
section could be understood since it is not in the scaling region, while the correction for $N_f = 12$
would become important only when the data outside of the scaling region were included. Although
it is obvious within the current data we can not discriminate both possibilities between the strongly
coupled conformal theory ($\gamma \sim 1$) and the chiral broken theory with approximate hyperscaling, the
tendency of $\gamma_{\text{eff}}$ found in $N_f = 8$ is indicative of a walking gauge theory.

4.1 Effective $\gamma$ from Dirac eigenvalues

Another way to calculate an effective $\gamma$ is to use the spectrum of the Dirac eigenvalues. From
the density of eigenvalues, $\rho(\lambda)$, with Dirac eigenvalue $\lambda$, the scaling law of $\rho(\lambda)$ is given as
$\rho(\lambda) \propto \lambda^{-\gamma/2}$. Thus we can obtain a scale-dependent mass anomalous dimension [7]. We define an
effective anomalous dimension from Dirac eigenvalues as

$$\frac{3 - \gamma_{\text{eff}}(\lambda)}{1 + \gamma_{\text{eff}}(\lambda)} = \frac{\ln\rho(\lambda + \Delta) - \ln\rho(\lambda)}{\ln(\lambda + \Delta) - \ln\lambda}.$$

(4.1)

We show the result for the smallest two fermion masses with $\Delta = 0.004$ in Fig. 5. We find $\gamma_{\text{eff}}(\lambda \sim
0) \sim 3$, which is consistent with a non-zero chiral condensate suffering from a non-zero fermion
mass effect. Looking at small $\lambda (> m_f)$, we estimate $0.5 < \gamma_{\text{eff}}(\lambda) \leq 1$ for $0.03 \leq \lambda \leq 0.1$. This is
roughly consistent with the one obtained from hadron spectra, but it requires a more careful study.

5. Flavor-singlet pseudoscalar mass

Here we would like to investigate the flavor-singlet pseudoscalar ($\eta'$). The $\eta'$ meson would be
a NG-boson of the axial $U(1)$ symmetry of QCD, while its mass is larger compared to the flavor
non-singlet pseudoscalar ($\pi$), which can be attributed to the axial $U(1)$ anomaly, where the $N_f$ factor manifests in the anomaly contribution. The axial anomaly relation tells that the topology of QCD can also play an important role in the $\eta'$ meson mass, so that an investigation of the $N_f$ dependence of the mass is important to understand QCD. We use a topological charge density operator $q(x)$ to calculate the two-point correlation function of the $\eta'$ meson. We use the gradient flow method [8] to improve the statistical accuracy, which was already adopted in the measurement of the topological charge and susceptibility [5]. We measure the correlation function $\langle q(x) q(y) \rangle$ for various flow time $t$. As a preliminary study we calculate the correlation function at $m_f = 0.02$ on $L = 36$ in $N_f = 8$. The result for the correlation function is shown in the left panel of Fig. 6, where $r = \|x - y\|$. The mass of the $\eta'$ meson ($M_{\eta'}$) is obtained by a fit with $\langle q(x) q(y) \rangle = c K_1(M_{\eta'} r)/r$, where $K_1(x)$ is a modified Bessel function and $c$ is a constant. We estimate an effective mass from a fit with range $[r, r+0.5]$ using an asymptotic form of the above function. The result of the effective mass is shown in the middle panel of Fig. 6. We find that a better plateau is obtained for larger flow time. To see flow time dependence of the mass, we carry out the fit with fixed fit range of $r = 6.5 - 10$. The result is shown in the right panel of Fig. 6, where we find a stable region for $t \leq 1$, and in this region a signal becomes better as $t$ increases. We quote a mass as $M_{\eta'} = 1.00(6)$ at $t = 0.6$ for $m_f = 0.02$. We obtain a ratio $M_{\eta'}/M_{\rho} = 3.1(2)$. This result is much larger than the real-life QCD. Our result suggests a heavy $\eta'$ meson, which might be due to a large fermion loop effect in many-flavor QCD.

---

3 Similar analyses have been done in quenched QCD [8] and $2 + 1$ flavor QCD [11].
6. Summary

We have studied the scaling properties of various hadron spectra in $N_f = 8$ QCD. We found that the ratios of the hadron spectra show a similar behavior to the $N_f = 4$ QCD, however, each quantity shows hyperscaling except for $M_\pi$, where $M_\pi$ obviously is outside a scaling region either in the conformal phase or in the chirally broken phase. We also found that a finite-size hyperscaling fit with universal $\gamma$ can work by adding a mass correction term. The fit result gives $\gamma \sim 1$ and a reasonable $\chi^2$ to dof. Further detailed analysis has been performed by studying an effective $\gamma$ for each hadron spectrum, which turns out to be useful to see a tendency towards the chiral limit. We found a qualitative difference between $N_f = 8$ and $12$; in $N_f = 8$ a universal value of $\gamma_{\text{eff}} \sim 0.4$ can be obtained in a smaller fermion mass region. This result might be indicative of $N_f = 8$ QCD being in the chirally broken phase. As a result, $N_f = 8$ QCD still possesses two possibilities of the strongly coupled conformal theory ($\gamma \sim 1$) and chirally broken theory with walking behavior. Thus $N_f = 8$ QCD is a good candidate for the walking technicolor model. We have also provided a calculation of the flavor-singlet pseudoscalar mass in $N_f = 8$ QCD. Using a gluonic operator and the gradient flow, we have obtained a good signal of the $\eta'$ mass for the first time in the many flavor QCD. Our result suggests a heavy $\eta'$ compared to real-life QCD.
