We calculate the nucleon-nucleon (NN) interaction up to sixth order (N^5LO) of chiral perturbation theory. Previous studies extended only up to N^3LO (fourth order) and typically showed a surplus of attraction, particularly, when the πN LECs from πN analysis were applied consistently. Furthermore, the contributions at N^2LO and N^3LO are both fairly sizeable, thus, raising concerns about the convergence of the chiral expansion. We show that the N^4LO contribution is repulsive and, essentially, cancels the excessive attraction of N^3LO. The N^5LO contribution turns out to be considerably smaller than the N^4LO one, hence, establishing the desired trend of convergence. The predictions at N^5LO are in excellent agreement with the empirical phase shifts of peripheral partial waves.
1. Introduction

The derivation of nuclear forces from chiral effective field theory has been a topic of active research for the past quarter century (see Refs. [1, 2] for recent reviews). By 1998, the evaluation of the nucleon-nucleon (NN) interaction up to next-to-next-to-leading order (N^2LO, third order in small momenta) was completed [3, 4, 5] and, by 2003, these calculations were extended to N^3LO [6, 7].

These N^3LO NN potentials complemented by chiral three-nucleon forces (3NFs) have been applied in calculations of few-nucleon reactions, the structure of light- and medium-mass nuclei, and nuclear and neutron matter—with, in general, a good deal of success. However, some problems continue to exist that seem to defy any solution. The most prominent one is the so-called ‘Ay puzzle’ of nucleon-deuteron scattering, which requires the inclusion of three-nucleon forces (3NFs). While the chiral 3NF at N^2LO slightly improves the predictions for low-energy N − d scattering [8], inclusion of the N^3LO 3NF deteriorates the predictions [9]. Based upon general arguments, the N^3LO 3NF is presumed weak, which is why one would not expect the solution of any substantial problems, anyhow. When working in the framework of an expansion, then, the obvious way to proceed is to turn to the next order, which is N^4LO (or fifth order). Some 3NF topologies at N^4LO have already been worked out [10, 11], and it has been shown that, at this order, all 22 possible isospin-spin-momentum 3NF structures appear. Moreover, the contributions are moderate to sizeable. What makes the fifth order even more interesting is the fact that, at this order, a new set of 3NF contact interactions appears, which has recently been derived by the Pisa group [12]. 3NF contact terms are of great interest from the point of view of the practitioner, because they are typically simple (as compared to loop contributions) and their coefficients are essentially free. Thus, at N^4LO, the Ay puzzle may be solved in a trivial way through 3NF (contact) interactions. Due to the great diversity of structures offered at N^4LO, one can also expect that other persistent nuclear structure problems may finally find their solution at N^5LO.

A principle of all EFTs is that, for reliable predictions, it is necessary that all terms included are to be evaluated at the order at which the calculation is conducted. Thus, if nuclear structure problems require for their solution the inclusion of 3NFs at N^4LO, then also the two-nucleon force involved in the calculation has to be of order N^4LO. This is one reason why we investigate the NN interaction at N^4LO. Besides this, there are also some more specific issues that motivate a study of this kind. From calculations of the NN interaction at N^2LO [4] and N^3LO [6], it is wellknown that there is a problem with excessive attraction, particularly, when for the c_i low-energy constants (LECs) of the dimension-two πN Lagrangian the values are applied that are obtained from πN analysis. It is important to know if this problem is finally solved when going beyond N^3LO. Last not least, also the convergence of the chiral expansion of the NN interaction is of general interest.

In our calculations, we show that the 2π- and 3π-exchange contributions at N^4LO are prevaingly repulsive and, thus, are able to fully compensate the excessive attraction of the lower orders [13]. However, we also notice that the N^2LO, N^3LO, and N^4LO contributions are all roughly of the same magnitude, raising legitimate concerns about the convergence of the chiral expansion of the NN-potential.

Therefore, we also investigate the NN-interaction at N^5LO (sixth power in small momenta) with the goal to obtain more insight into the convergence issue.
Besides this, the order N^5LO has other interesting features. At this order, a new set of NN-contact terms depending with the sixth power on momenta appears, bringing the total number of short-distance parameters to 50. This set includes then terms that contribute up to F-waves.

However, the focus of our present contribution is on peripheral partial waves with orbital angular momentum $L \geq 4$, which are exclusively ruled by the non-polynomial pion-exchange expressions constrained by chiral symmetry. Hence, this investigation is a test of the implications of chiral symmetry for the NN-interaction up to sixth order.

2. Pion-exchange contributions to the NN potential at N^4LO and N^5LO

Contributions are derived in terms of their spectral functions, from which the momentum-space amplitudes $V_\alpha(q)$ are obtained via subtracted dispersion integrals. For fifth order (N^4LO) contributions, the dispersion integrals read:

$$V_{C,S}(q) = -\frac{2q^6}{\pi} \int_{nm_\pi}^{\tilde{\Lambda}} d\mu \frac{\text{Im}V_{C,S}(i\mu)}{\mu^5(\mu^2 + q^2)},$$
$$V_T(q) = \frac{2q^4}{\pi} \int_{nm_\pi}^{\tilde{\Lambda}} d\mu \frac{\text{Im}V_T(i\mu)}{\mu^3(\mu^2 + q^2)},$$

(2.1)

and for sixth order, we use:

$$V_{C,S}(q) = \frac{2q^8}{\pi} \int_{nm_\pi}^{\tilde{\Lambda}} d\mu \frac{\text{Im}V_{C,S}(i\mu)}{\mu^7(\mu^2 + q^2)},$$
$$V_T(q) = -\frac{2q^6}{\pi} \int_{nm_\pi}^{\tilde{\Lambda}} d\mu \frac{\text{Im}V_T(i\mu)}{\mu^5(\mu^2 + q^2)}.$$  

(2.2)

The subscripts $C, S, T$ refer to central, spin-spin, and tensor force potentials, respectively. The thresholds are given by $n = 2$ for two-pion exchange and $n = 3$ for three-pion exchange. For $\tilde{\Lambda} \to \infty$, the above dispersion integrals yield the finite parts of loop-functions as in dimensional regularization, while for finite $\tilde{\Lambda} \gg nm_\pi$, we have the method known as spectral-function regularization (SFR). The purpose of the finite scale $\tilde{\Lambda}$ is to constrain the imaginary parts to the low-momentum region where chiral effective field theory is applicable.

2.1 Two-pion exchange contributions at N^4LO

The 2\pi-exchange contributions that occur at N^4LO are displayed graphically in Fig. 1. For part (a), the spectral functions are obtained by integrating the product of the leading one-loop $\pi N$ amplitude and the chiral $\pi \pi NN$ vertex proportional to $c_1$ over the Lorentz-invariant 2\pi-phase space. For part (b), the product of the one-loop $\pi N$ amplitude proportional to $c_1$ (see Ref. [10] for details) and the leading order chiral $\pi N$ amplitude are integrated over the 2\pi-phase space.

A few representative relativistic corrections are shown in Fig. 1(c). This group consists of diagrams with one vertex proportional to $c_1$ and one $1/M_N$ correction, where $M_N$ denotes the nucleon mass. Since in this investigation we count $Q/M_N \sim (Q/\Lambda_\chi)^2$ (with $\Lambda_\chi$ denoting the chiral symmetry breaking scale), these relativistic corrections are formally of order N^4LO.

Figure 2: Three-pion exchange contributions at N^4LO. The classification scheme of Ref. [14] is used. Notation as in Fig. 1.

2.2 Three-pion exchange contributions at N^4LO

The 3π-exchange of order N^4LO is shown in Fig. 2. The spectral functions for these diagrams have been calculated in Ref. [14]. We use here the classification scheme introduced in that reference and note that class XI vanishes. Moreover, we find that class X and part of class XIV make only negligible contributions. Thus, we include in our calculations only class XII and XIII, and the V_5 contribution of class XIV.

2.3 Two-pion exchange contributions at N^5LO

The 2π-exchange contributions that occur at N^5LO are displayed graphically in Fig. 3. For class (a), the spectral functions are obtained by integrating the product of the subleading one-loop πN-amplitude (see Ref. [10] for details) and the chiral ππNN-vertex proportional to c_1 over the Lorentz-invariant 2π-phase space.

A first set of 2π-exchange contributions at three-loop order, denoted by class (b), is displayed in Fig. 3(b). For this class of diagrams, the leading one-loop πN-scattering amplitude is multiplied with itself and integrated over the 2π-phase space.

Further 2π-exchange three-loop contributions at N^5LO, denoted by class (c), are shown in Fig. 3(c). For these the two-loop πN-scattering amplitude (which is of order five) would have to be folded with the tree-level πN-amplitude. To our knowledge, the two-loop elastic πN-scattering amplitude has never been evaluated in some decent analytical form. Note that the loops involved in the class (c) contributions include only leading order chiral πN-vertices. According to our experience such contributions are typically small. For these reasons we omit class (c) in the present calculation.

2.4 Three-pion exchange contributions at N^5LO

The 3π-exchange contributions of order N^5LO are shown in Fig. 4. The diagrams displayed in Fig. 4(a) are characterized by the presence of a subleading ππNN-vertex in each nucleon line. Using a notation introduced in Refs. [13, 14], we distinguish between the various sub-classes of diagrams by roman numerals. In Fig. 4(b), each 3π-exchange diagram includes the one-loop πN-amplitude (completed by the low-energy constants d_j). These contributions are, in general, small.

Ruprecht Machleidt

2.5 Four-pion exchange at N^5LO

The exchange of four pions between two nucleons occurs for the first time at N^5LO. The pertinent diagrams involve three loops and only leading order vertices, which explains the sixth power in small momenta. Three-pion exchange with just leading order vertices is known to be negligibly small, and so we expect four-pion exchange with leading order vertices to be even smaller. Therefore, we safely neglect this contribution.

3. Perturbative NN-scattering in peripheral partial waves

To obtain an idea of the physical relevance and implications of the contributions evaluated in Sec. 2, we will now calculate the impact of these on elastic NN-scattering in peripheral partial waves. Specifically, we will consider partial waves with orbital angular momentum \( L \geq 4 \) (i.e., \( G \)-waves and higher), because polynomial terms up to sixth power do not make any contributions to these angular momentum states. The \( L \geq 4 \) partial waves are sensitive only to the non-polynomial pion-exchange expressions governed by chiral symmetry.

The smallness of the phase-shifts in peripheral partial waves suggests that the calculation can be done perturbatively. This avoids the complications and possible model-dependences (e.g., cutoff-dependence) that the non-perturbative treatment with the Lippmann-Schwinger equation, necessary for low partial waves, is beset with.

Chiral symmetry establishes a link between the dynamics in the \( \pi N \)-system and the \( NN \)-system (through common low-energy constants). In order to check the consistency, we use the LECs for subleading \( \pi N \)-couplings as determined in analyses of low-energy elastic \( \pi N \)-scattering. Appropriate analyses for our purposes are contained in Refs. [10, 15], where \( \pi N \)-scattering has been calculated at fourth order using the same power-counting of relativistic \( 1/M_N \)-corrections as in the present work. Ref. [10] performed two fits, one to the GW [16] and one to the KH [17] partial wave analysis. In our present work, we apply the GW set. Moreover, we absorb the Goldberger-Treiman discrepancy into an effective value of the nucleon axial-vector coupling constant \( g_A = g_{\pi NN} f_{\pi}/M_N = 1.29 \).

The predictions for all \( G \) and \( H \) waves, are displayed in Fig. 5 in terms of colored bands that are generated by varying the SFR cutoff \( \tilde{\Lambda} \) between 700 and 900 MeV. The figure clearly reveals that, at N^3LO, the predictions are, in general, too attractive. The N^4LO contribution, essentially, compensates this attractive surplus. And turning to the result at N^5LO: it shows a moderate repulsive contribution bringing the final prediction right onto the data (i.e. empirical phase-shifts). Moreover, the N^5LO contribution is, in general, substantially smaller than the one at N^4LO, thus, establishing a clear signature of convergence of the chiral expansion.

Figure 5 includes only the three highest orders. However, a comparison between all orders is also of interest. Therefore, we show in Figs. 6 the contributions to phase shifts through all six chiral orders from LO to N^5LO. Note that the difference between the LO prediction (one-pion-exchange, dotted line) and the data (filled and open circles) is to be provided by two- and three-pion exchanges, i.e. the intermediate-range part of the nuclear force. How well that is accomplished is a crucial test for any theory of nuclear forces. NLO produces only a small contribution, but N^2LO creates substantial intermediate-range attraction (most clearly seen in \( ^1G_4 \) and \( ^3G_5 \)).
Figure 5: Phase-shifts of neutron-proton scattering in $G$ and $H$ waves at various orders as denoted. The colored bands show the variations of the predictions when the SFR cutoff $\tilde{\Lambda}$ is changed over the range 700 to 900 MeV. The filled and open circles represent the results from the Nijmegen multi-energy $np$ phase-shift analysis [18] and the GWU SP07 $np$-analysis [19], respectively.

Figure 6: Phase-shifts of neutron-proton scattering in $G$ waves at all orders from LO to N$^5$LO. A SFR cutoff $\tilde{\Lambda} = 800$ MeV is used. Empirical phase shifts are as in Fig. 5.
The nucleon-nucleon interaction up to sixth order in the chiral expansion

Ruprecht Machleidt

4. Conclusions

In this contribution, we have calculated $2\pi$- and $3\pi$-exchange contributions to the $NN$-interaction which occur at $N^4\text{LO}$ (fifth order) and $N^5\text{LO}$ (sixth order) of the chiral low-momentum expansion. The calculations are done in heavy-baryon chiral perturbation theory using the most general fourth order Lagrangian for pions and nucleons. We apply low-energy constants for subleading $\pi N$-coupling, which were determined from an analysis of elastic $\pi N$-scattering to fourth order using the same power counting scheme as in the present work. The spectral functions, which determine the $NN$-amplitudes via subtracted dispersion integrals, are regularized by a cutoff $\tilde{\Lambda}$ in the range 0.7 to 0.9 GeV. Besides the cutoff $\tilde{\Lambda}$, our calculations do not involve any adjustable parameters.

From past work on $NN$ scattering in chiral perturbation theory (see, e.g., Ref. [6]), it is well-known that, at $N^2\text{LO}$ and $N^3\text{LO}$, chiral $2\pi$-exchange produces far too much attraction. One important result of the present study is that the $N^4\text{LO}$ $2\pi$ and $3\pi$ contributions are prevailingly repulsive and, thus, compensate the excessive attraction of the lower orders.

On the other hand, the $N^2\text{LO}$, $N^3\text{LO}$, and $N^4\text{LO}$ contributions are all about of the same magnitude raising some concern about the convergence of the chiral expansion of the $NN$ amplitude. To obtain insight into this issue, we have also investigated the $NN$ interaction at $N^5\text{LO}$. Our calculations show that the contribution at $N^5\text{LO}$ is substantially smaller than the one at $N^4\text{LO}$, thus, establishing a clear signature of convergence. The $N^5\text{LO}$ two-loop $2\pi$-exchange contribution is the largest, while the corresponding three-loop contribution is small, but not negligible. Three-pion exchange is generally small at $N^5\text{LO}$. The phase-shift predictions in $G$ and $H$ waves, where only the non-polynomial terms governed by chiral symmetry contribute, are in excellent agreement with the data.

This investigation represents the most comprehensive (and successful) test of the implications of chiral symmetry for the $NN$-system.
