Pion photoproduction constitutes a prototype process, which allows for the study of the electro-weak decay of a QCD-unstable state, the $\rho$ resonance. It is also the most straightforward process to investigate such (resonant) transition matrix elements in lattice QCD. We performed a lattice calculation of the process $\pi\pi \rightarrow \rho \rightarrow \pi\gamma$, at presently the lightest pion mass of 317 MeV and in a large box of size $(3.6 \text{ fm})^3$. In addition to outlining the method for our calculation, we give account of our analysis of systematic uncertainties, with focus on parametrization dependence of the $P-$wave phase shift and the analytic continuation of our lattice data to the $\rho$ resonance pole to extract the coupling $|G_{\rho\pi\gamma}| = 0.0802 (38)$.

1. Introduction

The calculation of electro-weak matrix elements of QCD-unstable hadronic states has been of long-standing interest to lattice QCD. Calculations in lattice QCD are performed in Euclidean, discretized space-time and in a finite volume box of size $L^3 \times T$. Within this setup, $S$-matrix elements are not directly accessible from lattice $n$-point correlation functions. Indeed, Maiani and Testa’s no-go theorem [1] stated early on, that inescapable final state interactions of multi-hadron states in finite volume prevent a straight-forward interpretation of matrix elements from the lattice in terms of continuum and infinite-volume amplitudes. This issue of proper normalization of lattice correlation functions during conversion to infinite volume has been addressed for the case of the $K$ to $\pi\pi$ transition in the pioneering work by Lellouch and Lüscher [2], based on the Lüscher quantization condition [3] for 2-hadron states in finite volume and the mapping of the finite-volume lattice spectrum to the elastic scattering amplitude. More recently, Briceño, Hansen and Walker-Loud (BHWL) generalized the method for these $1 \rightarrow 2$ transitions to arbitrary current insertions between the single- and two-hadron initial and final state, with arbitrary momentum transfer, as well as fields with arbitrary spin [4, 5]. A prototype calculation for the $\pi\gamma \rightarrow \pi\pi$ transition was presented in [6, 7]. In this contribution we present our calculation of the pion-photo-transition amplitude at so far lightest pion mass of 317 MeV. We focus in particular on the $\rho$-resonance region to extract $\rho - \pi - \gamma$ coupling and the photoproduction cross-section. The further implementation of the BHWL formalism opens the exciting prospect to study more complicated electro-weak matrix elements for resonant transitions, such as for nucleon-pion and nucleon-kaon.

2. Resonant pion-photoproduction process

The pion-photo production amplitude across the $\rho$-resonance region is the most straightforward example to start with and we give a pictorial representation in Fig. 1. In continuum and infinite volume QCD, the decomposition of the matrix element is governed by Lorentz symmetry and given by

$$\langle \pi\pi | J^\mu(0) | \pi \rangle = \frac{2i \gamma_{\pi\gamma\rightarrow\pi\pi}(q^2, s)}{m_\pi} \gamma^\nu \epsilon_{\alpha\beta} \epsilon_{\nu}(P, m) (p_\pi) \alpha P_\beta \ . \tag{2.1}$$

$P$ denotes the total 4-momentum of the final 2-pion state, $p_\pi$ that of the initial single-pion state, $\sqrt{s}$ the invariant mass and $\epsilon$ the polarization 4-vector for the $\pi\pi$ $P$-wave state $\langle l = 1, m \rangle$. 

---

Figure 1: Diagram representation for resonant photoproduction with $g_{\rho\pi\pi}$ coupling (left vertex) and photo-transition amplitude.
Splitting off the kinematic factors introduces the photo-transition amplitude \( V_{\pi\gamma \rightarrow \pi\pi} \) depending on invariant mass and photon momentum transfer \( q^2 = (P - p_\pi)^2 \). Given the normalization with inverse pion mass chosen in (2.1) and the normalization of single- and 2-pion states \(^1\), the amplitude \( V_{\pi\gamma \rightarrow \pi\pi} \) has units of MeV\(^{-1}\).

The residue of the elastic \( \pi\pi \) isospin-1 scattering amplitude \( T_{\pi\pi \rightarrow \pi\pi} \) at the \( \rho \) resonance pole \( s_p \approx m_\rho^2 + i m_\rho \Gamma_\rho \) defines the coupling \( G_{\rho\pi\pi} \): in the vicinity of \( s_p \) the scattering amplitude is given by

\[
T_{\pi\pi \rightarrow \pi\pi} = \frac{16\pi \sqrt{s}}{k \cot(\delta(s)) - i \sim \frac{s_p - s}{s_p}} \quad (2.2)
\]

with \( \pi\pi \) center-of-mass momentum \( k \) and elastic scattering phase shift \( \delta(s) \).

The photo-production amplitude has a pole at the \( \rho \) resonance as well. Moreover, its complex phase is determined by the final state interaction of the 2 pions, i.e. by the \( \pi\pi \) scattering phase shift, according to Watson’s Theorem. Thus, factoring out the pole and observing the phase \( V_{\pi\gamma \rightarrow \pi\pi} \) can be written in terms of the form factor \( F(q^2, s) \) in Eq. (2.3),

\[
V_{\pi\gamma \rightarrow \pi\pi}(q^2, s) = \sqrt{\frac{16\pi}{k\Gamma(s)} \frac{F(q^2, s)}{\cot(\delta(s)) - i \sim \frac{s_p - s}{s_p}}} \quad (2.3)
\]

The calculation of the transition amplitude for the process \( \pi\gamma \rightarrow \rho \) requires a matrix element with the \( \rho \) as final state. By virtue of decay to two pions\(^2\) the \( \rho \) is QCD-unstable and the normalization of the matrix elements obtained from lattice QCD in finite volume requires the proper residual of the fully dressed 2-pion propagator arising from the infinite sequence of elastic rescattering, which is unavoidable in the finite lattice volume. The corresponding finite to infinite volume conversion has been introduced for the \( K \rightarrow \pi\pi \) process in [2], has recently been generalized as the Briceño-Hansen-Walker-Loud (BHWL) formalism [4, 5] and accommodates the case considered here, which was first applied in [6, 7]. The BHWL work-flow we follow is captured in the chart 2: the finite-volume spectrum in the \( \rho \) channel is determined from the lattice calculation and converted into the scattering amplitude at the discrete finite-volume energy levels via the Lüscher quantization condition. Together with the finite-volume \( 1 \rightarrow 2 \) matrix elements input, the BHWL formalism gives the corresponding infinite-volume transition amplitude evaluated at the lattice energy levels, which are subsequently analytically continued to the \( \rho \) resonance pole. The pole location we obtain from describing our scattering amplitude data with the Breit-Wigner form and variations thereof.

\(^1\)The normalization is chosen as follows:

\[
\langle \pi(p) | \pi(q) \rangle = 2E(p) (2\pi)^3 \delta^{(3)}(\vec{p} - \vec{q})
\]

\[
\langle \pi\pi, P, \vec{k}_{CM} | \pi\pi, P', \vec{k}'_{CM} \rangle = 2E_1 2E_2 (2\pi)^3 \delta^{(3)}(\vec{k} - \vec{k}') (2\pi)^3 \delta^{(3)}(\vec{p} - \vec{p}' + \vec{k} + \vec{k}')
\]

\(^2\)Below the \( KK \) and \( 4\pi \) threshold.
4. Elastic $\pi\pi$ isospin-1 $p-$wave phase-shift

To extract the lattice spectrum in the $\rho$-channel $I(J^{P}) = 1(1^-)$ we solve the generalized eigenvalue problem (GEVP) [8, 9] for correlation matrices built from a variational basis of single hadron (quark-bilinear, or $\rho$-type) and two-hadron ($\pi\pi$-type) interpolating fields. The matrices of 2-point correlation functions are considered per $\pi\pi$ center-of-mass momentum and projected to irreducible representations (irreps) of the lattice, finite-volume rotational symmetry group $O_h$ and subgroups thereof.

The 15 kinematic points in invariant \( \pi \pi \) mass \( \sqrt{s} \) are fitted to Breit-Wigner models denoted “BWI” and “BWII”

\[
\text{BWI} \quad \Gamma_I(s) = \frac{g_{\rho \pi \pi}^2 k^3}{6\pi} \frac{k^3}{s} (4.1)
\]

\[
\text{BWII} \quad \Gamma_{II}(s) = \frac{g_{\rho \pi \pi}^2 k^3}{6\pi} \frac{1 + (k_R r_0)^2}{1 + (k_R r_0)^2} (4.2)
\]

BWII amends the standard BWI form by a Blatt-Weisskopf barrier factor with radius \( r_0 \). The results for the fit parameters are given in the table above. With BWII we do not detect significant deviations from the simple BWI form. Yet in the BHWL analysis to follow, we keep both parametrizations to check for systematic uncertainties originating from the choice of interpolation model.

5. Photoproduction amplitude

The finite-volume transition matrix element \( \langle \pi, \vec{p}_\pi \mid J_\mu(0, \vec{Q}) \mid n, \vec{P}, \Lambda, r \rangle \) is determined for the \( n \)th energy level with a given total momentum \( \vec{P} \) of the \( \pi \pi \) system, which is projected to row \( r \) within irrep \( \Lambda \). We obtained it from 3-point functions using the variationally optimized interpolators, that result from the GEVP analysis, with the insertion of the multiplicatively renormalized (\([111]\)) electromagnetic current \( J_\mu = Z_V \left( \frac{2}{3} \bar{u} \gamma_\mu u - \frac{1}{3} \bar{d} \gamma_\mu d \right) \) between initial 2-pion and final single-pion state interpolator as given in Eq. (5.1)

\[
\Omega^{\vec{p}_\pi, \Lambda, \mu, r}_3(t_\pi, t_J, t_{\pi\pi}) = \langle \phi_{\pi}^{\vec{p}_\pi}(t_\pi) J_\mu(t_J, \vec{q}) \phi_{\pi}^{\vec{p}_\pi}(t_{\pi\pi}, \vec{P}) \rangle. (5.1)
\]

For large time separations between final / initial state excitation and current insertion \( t_{\pi\pi} - t_J / t_\pi - t_J \) the ensuing ratio (5.2) of 3-point and 2-point functions is proportional to the desired finite-volume
matrix element up to excited state contamination.

\[ R_{\mu,n}^{P,\Lambda,\tau}(t_\pi, t_J, t_{\pi\pi}) = \frac{\mathcal{O}_{3,\mu,n}^{P,\Lambda,\tau}(t_\pi, t_J, t_{\pi\pi}) \mathcal{O}_{3,\mu,n}^{P,\Lambda,\tau}(t_{\pi\pi}, t_J, t_{\pi\pi})}{C_\pi^{2\mu}(t_\pi - t_{\pi\pi}) C_\pi^{2\mu}(t_{\pi\pi} - t_{\pi\pi})} \]

\[ t_{\pi\pi} \sim t_J \text{ large} \]

\[ |\langle \pi, \vec{p}_\pi \mid J_\mu(0, \vec{Q} = \vec{p}_\pi - \vec{P}) \mid n, \vec{P}, \Lambda, r \rangle |^2_{FV} \]

(5.2)

We depict the prototype Wick contractions used to build the 3-point functions in Fig. 4. The partially transparent top left and center diagrams are quark-disconnected with the vector current loop. The contribution of those diagrams are statistically insignificant for the signal at our present level of accuracy and neglected in our calculation. An exemplary subset of ratios for total momenta $|\vec{P}| = \sqrt{3} 2\pi / L$ and $|\vec{P}| = 2\pi / L$ for several irreps together with the fits to a constant is shown in the 3 left-hand columns of Fig. 5: the three columns correspond to source-sink time separation $t_\pi - t_{\pi\pi} = 8a$, $10a$, $12a$. The right-most column shows the stability of the constant fit under variation of data selected into the fit from the set of source-sink separations and number of data points around the center $t_J = (t_\pi - t_{\pi\pi}) / 2$.

Following the BHWL formalism in Fig. 2, we convert the finite-volume matrix element to its infinite-volume counterpart at the same kinematic parameters using the Lellouch-Lüscher factor

\[ \frac{|\langle \pi, \vec{p}_\pi \mid J_\mu(0) \mid s, q^2; \vec{P}, \Lambda, r \rangle_{IV}|^2}{|\langle \pi, \vec{P} \mid J_\mu(0, \vec{Q}) \mid n, \vec{P}, \Lambda, r \rangle_{FV}|^2} = \frac{1}{2E_{n}^{\mu,\Lambda}} \frac{16\pi \sqrt{s_{n}^{P,\Lambda}}}{k_{n}^{P,\Lambda}} \left( \frac{\partial \delta}{\partial E} + \frac{\partial \phi^{P,\Lambda}}{\partial E} \right) \bigg|_{E = E_{n}^{\mu,\Lambda}} \]

(5.3)

In eq. (5.3) $\delta$ denotes the $\pi\pi$ elastic phase shift, $k_{n}^{P,\Lambda}$ the $\pi\pi$ center of mass relative momentum and $\phi^{P,\Lambda}$ is an analytically known function from the Lüscher quantization condition. We show the numerical values for the Lellouch-Lüscher (LL) factor as a function of $\pi\pi$ center of mass energy for our setup in Fig. 6 for all $\pi\pi$ total momenta and irreps used in our calculation. Since the LL factor depends on the interpolation of phase shift data, we show the values for both BWI (blue solid line) and BWII (red dashed line). To appreciate the impact of the scattering phase derivative on the LL factor, in black solid line we give the contribution from $\phi^{P,\Lambda}$ in eq. (5.3) alone. The left-hand plot in Fig. 7 summarizes our lattice data [12] for the infinite-volume transition amplitude $\gamma_{\pi\gamma \rightarrow \pi\pi}(q^2, s)$ ( the complex phase as given by Watson’s Theorem is omitted ): central values are shown by gray columns, and magenta boxes give the one-standard deviation intervals. To parameterize the data...
Figure 5: Selection of finite volume matrix element data and fits.

Figure 6: Numerical values for the Lellouch-Lüscher factor
we employ a Taylor expansion of the form factor $F$ (cf. eq. (2.3)) in $s$ and $q^2$ represented by the variables $\mathcal{J} = (s - m_R^2)/m_R^2$ and $z = \frac{\sqrt{s} - q^2 - \sqrt{s} - m_0}{\sqrt{s} - q^2 + \sqrt{s} - m_0}$:

$$F(q^2, s) = \frac{1}{1 - \frac{q^2}{m_\rho^2}} \sum_{n=0}^{N} \sum_{m=0}^{M} A_{nm} z^n \mathcal{J}^m,$$  

(5.4)
width of the $\rho$ as

$$\Gamma(\rho \rightarrow \pi \gamma) = \frac{2}{3} \alpha \left( \frac{(m_{\rho}^2 - m_{\pi}^2)}{2m_{\rho}} \right)^3 \frac{|G_{\rho\pi\gamma}|^2}{m_{\pi}^2}$$

(5.6)

classified by the coupling $G_{\rho\pi\gamma}$ introduced in eq. (2.2). For the coupling we find

$$|G_{\rho\pi\gamma}| = 0.0802(32)(20),$$

(5.7)

where the first uncertainty is statistical and systematic and the second uncertainty represents the model dependence for $F_{\pi\gamma\rightarrow\rho}(0)$, which is shown in detail for all accepted parametrizations of the form factor in the right-hand plot of Fig. 9. Using physical, PDG-values [13] for the particle masses to have realistic kinematics and assuming a negligible pion-mass dependence of the dimensionless coupling $G_{\rho\pi\gamma}$ we thus obtain for the radiative decay width

$$\Gamma(\rho \rightarrow \pi \gamma)_{\text{lat}} = 84.2(6.7)(4.3)\text{ keV} \quad \text{[physical $m_\pi, m_\rho$]}$$

$$\Gamma(\rho \rightarrow \pi \gamma)_{\text{exp}} = 68(7)\text{ keV} \quad \text{[13]},$$

in reasonable agreement with experiment.
6. Outlook

Our continuing work focuses on calculations at smaller pion mass ($m_\pi \sim 170\text{MeV}$) to investigate the chiral extrapolation as well as smaller lattice spacing to check for lattice artifacts. Moreover, using our extended analysis framework and our already obtained data, we perform the BHWL analysis for the heavy meson decay processes $B \to (\rho \to \pi\pi) \ell \bar{\nu}_\ell$ and $B \to (K^* \to K\pi) \ell \ell$.
