HPQCD Collaboration

We present results of the first lattice QCD calculations of $B_c \rightarrow B_s$ and $B_c \rightarrow B_d$ weak matrix elements. Results are derived from correlation functions computed on MILC Collaboration gauge configurations with lattice spacings between 0.12 [fm] and 0.06 [fm] including 2+1+1 flavours of dynamical sea quarks in the Highly Improved Staggered Quark (HISQ) formalism. Form factors across the entire physical $q^2$ range are then extracted and extrapolated to the physical-continuum limit. Two different formalisms are employed for the bottom quark: non-relativistic QCD (NRQCD) and heavy-HISQ. Checking agreement between these two approaches is an important test of our strategies for heavy quarks on the lattice.

37th International Symposium on Lattice Field Theory - Lattice2019
16-22 June 2019
Wuhan, China
1. Introduction

The semileptonic weak decays $B_c^+ \rightarrow B_s^0 \ell \nu$ and $B_c^+ \rightarrow B^0 \ell \nu$ proceed via tree-level flavour changing processes $c \rightarrow sW^+$ and $c \rightarrow dW^+$ parametrised by the Cabbibo-Kobayashi-Maskawa (CKM) matrix of the Standard Model. Associated weak matrix elements can be expressed in terms of form factors which capture the non-perturbative QCD physics. Precise determination of the normalisation and $q^2$ dependence of these form factors from lattice QCD will allow comparison with future experiment to deduce the CKM parameters $V_{cs}$ and $V_{cd}$.

The $B_c^+ \rightarrow B_s^0 \ell \nu$ and $B_c^+ \rightarrow B^0 \ell \nu$ decays involve the practical complication of a heavy spectator quark. Care must be taken in placing such a particle on the lattice to avoid large discretisation effects. We carry out one study with a valence NRQCD $b$ quark, allowing for computations with physically massive $b$ quarks, and a complementary calculation using the fully relativistic approach of HPQCD’s heavy-HISQ method [2] which involves calculations for a set of quark masses on ensembles of fine lattices at a variety of lattice spacings, enabling a fit from which the physical result at the $b$ quark mass in the continuum can be determined. The consistency of the NRQCD and heavy-HISQ approaches is demonstrated by comparing the form factors extrapolated to the physical-continuum limit.

The form factors $f_0$ and $f_+$ parametrise the continuum weak matrix element

$$
\langle B_{s(d)}(p_2)|V^\mu|B_c(p_1)\rangle = f_0(q^2)\left[\frac{M_{B_s}^2 - M_{B_{s(d)}}^2}{q^2}q^\mu\right] + f_+(q^2)\left[p_2^\mu + p_1^\mu - \frac{M_{B_c}^2 - M_{B_{s(d)}}^2}{q^2}q^\mu\right]
$$

and are constructed from the matrix elements by fitting the correlator data to a sum of real exponentials, where $q = p_1 - p_2$ is the 4-momentum transfer. By calculating correlators at a range of transfer momenta on lattices with different spacings and quark masses, continuum form factors at physical quark masses are obtained.

2. Lattice Methodology

2.1 Lattice Parameters

Ensembles with $2+1+1$ flavours of HISQ sea quark generated by the MILC collaboration [3, 4, 5] are described in table 1. The Symanzik improved gluon action used is that in [6] where the gluon action is improved perturbatively through $O(\alpha_s a^2)$ to account for dynamical HISQ sea quarks. HISQ [7] is used for all other valence flavours. Masses used for the HISQ propagators calculated with the MILC code [8] on these gluon configurations are tabulated here also. Our calculations feature physically massive strange quarks and equal mass up and down quarks, with a mass denoted by $m_l$, with $m_l/m_s = 0.2$ and also the physical value $m_l/m_s = 1/27.4$ [9].

We work in the frame where the $B^+_c$ is at rest, and momentum is inserted into the strange and down valence quarks through twisted boundary conditions [13] in the $(1 1 1)$ direction. For the heavy-HISQ calculation, we use heavy quark masses up to $am_b = 0.8$.

2.2 Correlators

Random wall source [14] HISQ propagators are combined with random wall source NRQCD $b$ propagators to generate $B^+_c$ and $B^0_{s(d)}$ 2-point correlator data. The HISQ charm propagator in the 3-
of the form factors. The heavy-HISQ calculation used sets 3, 5 and 6.

Table 1: Parameters for the MILC ensembles of gluon field configurations. The lattice spacing $a$ is determined for the Wilson flow parameter $w_0$ given in lattice units for each set in column 2 where values were obtained from [10] on sets 1 to 5 and [11] on set 6. The physical value $w_0 = 0.1715(9)$ was fixed from $f_K$ in [12]. The very-coarse lattices, sets 1 and 2, have $a \approx 0.15$ [fm], and the coarse lattices, sets 3 and 4, have $a \approx 0.12$ [fm]. Sets 5 and 6 have $a \approx 0.09$ [fm] and $a \approx 0.06$ [fm] respectively. Sets 1, 3, 5 and 6 have unphysically massive light quarks such that $m_l/m_s = 0.2$. Sets 1 to 5 were used in the NRQCD calculation of the form factors. The heavy-HISQ calculation used sets 3, 5 and 6.

point correlator, represented diagrammatically in figure 1, uses the random wall bottom propagator as a sequential source.

![Figure 1: 3-point correlator $C_{3pt}(t, T)$.](image)

The correlators are fit to the following functions through use of the *corrfitter* package [15]. The fit seeks to minimise an augmented $\chi^2$ as described in [16, 17, 18]. The functional forms

\[
C_{2pt}^{B_{i,d}}(t) = \sum_i a[i]^2 e^{-E_{a}[i]t} - \sum_i a_o[i]^2 (-1)^t e^{-E_{a_o}[i]t}
\]

\[
C_{2pt}^{B_{i}}(t) = \sum_j b[j]^2 e^{-E_{b}[j]t} - \sum_j b_o[j]^2 (-1)^t e^{-E_{b_o}[j]t}
\]

(2.1)

\[
C_{3pt}(t, T) = \sum_{i,j} a[i] e^{-E_{a}[i]t} V_{mn}[i, j] b[j] e^{-E_{b}[j](T-t)} - \sum_{i,j} (-1)^{T-t} a[i] e^{-E_{a}[i]t} V_{mn}[i, j] b_o[j] e^{-E_{b_o}[j](T-t)}
\]

\[
- \sum_{i,j} (-1)^t a_o[i] e^{-E_{a_o}[i]t} V_{mn}[i, j] b[j] e^{-E_{b}[j](T-t)} + \sum_{i,j} (-1)^T a_o[i] e^{-E_{a_o}[i]t} V_{mn}[i, j] b_o[j] e^{-E_{b_o}[j](T-t)}
\]

(2.2)

follow from the spectral decomposition of the Euclidean correlators with additional oscillatory contributions due to the coupling of different tastes of staggered quark. The matrix elements are
related to the fit parameters $V_{mn}(0,0)$ through $\sqrt{2E_{B_{s(d)}}}V_{mn}(0,0) = \langle B_{s(d)} | J | B_c \rangle$, where $J$ is the relevant operator that facilitates the $c \rightarrow s(d)$ flavour transition. On each set, the 2-point and 3-point correlator data for both $c \rightarrow s$ and $c \rightarrow d$ at all momenta is fit simultaneously to account for all possible correlations. Matrix elements and energies are then extracted.

### 2.3 Extracting the form factors

For both HISQ and NRQCD spectator quarks, the HISQ action is used for the quarks that participate in the current. Hence, the current normalisation can be determined non-perturbatively by making use of the Partially Conserved Vector Current (PCVC) Ward identity

$$\partial_\mu V^\mu = (m_c - m_{s(d)}) S \quad (2.3)$$

relating the conserved (point-split) $c \rightarrow s(d)$ lattice vector current and the local lattice scalar density $S$. We choose local lattice operators only, thus equation (2.3) must be adjusted by a single renormalisation factor $Z_V$ associated with the local lattice vector current giving

$$q_\mu \langle B_{s(d)} | V^\mu | B_c \rangle Z_V = (m_c - m_{s(d)}) \langle B_{s(d)} | S | B_c \rangle. \quad (2.4)$$

Combining equations (1.1) and (2.4) gives a determination of $f_0$ solely in terms of the scalar density matrix element through

$$f_0(q^2) = \langle B_{s(d)} | S | B_c \rangle \frac{m_c - m_{s(d)}}{M_{B_c}^2 - M_{B_{s(d)}}^2}. \quad (2.5)$$

Thus, we are concerned with insertions of the local scalar density $J = S$ as well as the local vector current $J = V$. Once $f_0$ is determined, $f_+$ is obtained using equation (1.1).

### 3. Results

Figure 2 shows data for the form factor $f_0$ for the $B_c \rightarrow B_s$ process. The data for all momenta on all the lattices is fit simultaneously to a functional form which allows for dependence on the lattice spacing $a$ and mistuned bare quark masses. The fit is carried out using the *lsqfit* package [19] that implements a least-squares fitting procedure. It is convenient to map the semileptonic region $0 < q^2 < (M_{B_c} - M_{B_{s(d)}})^2$ to within the unit circle through

$$t_{\pm} = \frac{(M_{B_c} \pm M_{B_{s(d)}})^2}{2},$$

$$z = \frac{\sqrt{t_+ - q^2} - \sqrt{t_+ - t_0}}{\sqrt{t_+ - q^2} + \sqrt{t_+ - t_0}}, \quad (3.1)$$

so that the form factors can be approximated by a truncated power series in $z$. The parameter $t_0$ is chosen to be 0, thus the points $q^2 = 0$ and $z = 0$ coincide. Expressing the form factor as a polynomial in $z$ was a suitable approach for $D \rightarrow K(\pi)$ in [20] since the polynomial coefficients where $\mathcal{O}(1)$. The value $z(q^2 = t_-)$ is two orders of magnitude smaller than in [20], yet the ranges of physical $q^2$ are comparable since $t_{B_c \rightarrow B_s}^{B_s \rightarrow K} = \mathcal{O}(1)$. Hence, $z$ in equation (3.1) must be rescaled appropriately to ensure that the polynomial coefficients are $\mathcal{O}(1)$, a desirable property.
when setting prior distributions. In this study, we rescale $z$ and define $z_p(q^2) = z(q^2) / |z(M_{res}^2)|$, where $M_{res}$ is the mass of the nearest resonance.

With an NRQCD spectator quark, the form factor fit takes the form

$$f(q^2) = P(q^2) \sum_{n=0}^{3} b^{(n)} z_p^n,$$  

(3.2)

where the pole structure is represented by a factor $P(q^2) = (1 - q^2 / M_{res}^2)^{-1}$ multiplying a polynomial whose coefficients are

$$b^{(n)} = A^{(n)} \left\{ 1 + B^{(n)} (a_{mc} / \pi)^2 + C^{(n)} (a_{mc} / \pi)^4 \right\}$$  

(3.3)

with further terms that account for quark mass mistunings.

The heavy-HISQ data requires a fit form that accounts for $(a_{mc})^{2n}$ discretisation effects as well as physical dependence on $m_h$. Motivated by HQET we express this physical heavy mass dependence as a power series in $\Lambda_{QCD} / M_H$. The form factor data from heavy-HISQ is fit to

$$f(q^2) = P(q^2) \sum_{n,i,j,k=0}^{3} A_{ijk}^{(n)} \left( \frac{a_{mc}}{\pi} \right)^{2i} \left( \frac{a_{mb}}{\pi} \right)^{2j} \Delta_{Hc}^{(k)},$$  

(3.4)

where, for $k = 0$, $\Delta_{Hc}^{(0)} = 1$ and, for $k \neq 0$,

$$\Delta_{Hc}^{(k)} = \left( \frac{\Lambda_{QCD}}{M_{Hc}} \right)^k - \left( \frac{\Lambda_{QCD}}{M_B} \right)^k.$$  

(3.5)

The mistuning terms are again omitted for brevity. Finally, the kinematic relation $f_0(0) = f_+(0)$ is imposed on the fit as a constraint alongside the data.

The form factor $f_+$ for the $B_c \to B_s$ and $B_c \to B_d$ processes, at the physical-continuum limit, from NRQCD and heavy-HISQ is shown in figure 3. Plotted alongside the functions from the

**Figure 2:** $f_0$ form factor data for $B^+_c \to B^0_s \nu \bar{\nu}$ from both the NRQCD and heavy-HISQ approaches. Filled in circles denote NRQCD form factor data.
heavy-HISQ and NRQCD calculations is a function arising from a chained fit where the $A^{(n)}_{000}$ from the heavy-HISQ fit were used as prior distributions for the $A^{(n)}$ in the form factor fit forms in the NRQCD study. This chained fit has $\chi^2$/d.o.f. = 1.4 and is consistent with both the separate fits. The chained fit is labelled ‘NRQCD from heavy-HISQ’ in figure 3.
